This woman was an intellectual, well-read and thoughtful, a professional who told me with great pride about students she had trained; and she reveals a remarkable separation between her physical self and her "real" nonphysical self in imagining conversations with her own body parts. She also was a lonely person, with no family, and she had recently lost her best friend to a recurrence of breast cancer; her self-rating of health was "fair."

Religion is a complicated thing. People seek help from it when they are in trouble, especially when they have been brought up with a traditional faith, and especially when that religious tradition speaks to their situation. So the data show, quite straightforwardly, that people with greater disability were more likely to say they had sought help from religion. The respondents' own words, which I have used liberally, seem to convey a consistent theme that people turn to religion in need, and that one of the ways religion helps them is by letting them "rise above" their problems, so to speak, by putting them in a context in which the physical body does not matter that much.

Well, I know that some people if they believe in God and if they believe in prayer would pray to be relieved of their pain. But I always could see others that were worse off than me so when I went to pray, I couldn't pray for myself when the guy next door was so much worse so I wound up praying for him and it helps to take my mind off my own problems. (54-year old Roman Catholic woman who had had a stroke)

In these voices speaking of religion and health there are themes of new insight, of the relevance of religious beliefs to some of the most challenging and threatening of human experiences, and of the growth and development of the self. Above all, they speak of the authenticity of these experiences. Self-ratings of health, another expression of subjective experience, are being taken more and more seriously by researchers because of their apparent ability to communicate vital health information. Their relationship with eventual health outcomes should also underscore for us the validity and importance of the patient/respondent's point of view, a view some have argued is increasingly absent in the historical development of Western medicine (Reiser 1993).

The coherence of these voices belies the contradictions in the relationship between religion and health presented at the beginning of this article. People say they do turn to religion in crises of illness, and religion also seems to be associated with more positive views of health when the spiritual self becomes more prominent. Ultimately, however, longitudinal data are necessary to establish causal order in these processes that appear contradictory at the cross section.

APPENDIX: Sense of Self Scale

Here are some ways in which people think about themselves. For these questions, I would like you to think about your whole life, not just the way you are today.

On a scale of 0 to 10, tell me to what extent you think of yourself as:

1. a musical person?
2. a reader?
3. an artistic person?
4. a social person?
5. an intellectual?
6. a family person?
7. a conversationalist?
8. a writer?
9. a spiritual person?*
10. someone who is good with numbers?
11. someone who is good at solving problems or puzzles?
12. a scientific person?
13. a professional?
14. someone with a sense of humor?
15. a religious person?*

* Treated as a separate scale for the purpose of this study.

Religious Resources and Church Growth*

Abstract

This article models the growth of religious organizations as a "product" derived from inputs of time and money. Using measures of church attendance and contributions as proxies for time and money resources, we predict membership growth at the levels of both individual congregations and entire denominations. Our data also highlight the tremendous variation in rates of resource mobilization across different denominations. In each of the past two decades, the decline of liberal/mainline denominations and the growth of their more strict/conservative counterparts can be modeled largely in terms of the radically different amounts of time and money that they demand and receive from members.

Why do some religious organizations grow rapidly while others lose members? Or, to address the primary historic trend in American religion, why have theologically conservative denominations prospered while the more liberal, "mainline" bodies declined?

More than 20 years ago, Dean Kelley ([1972] 1986) proposed an answer to this question. His now-classic study, *Why Conservative Churches Are Growing*, identified organizational "strictness" as the distinguishing feature of strong churches and thus traced the success of conservative denominations to their demands for complete loyalty, unwavering belief, and rigid adherence to a distinctive lifestyle. Recent work has used rational choice theory to formalize parts of Kelley's thesis and to demonstrate how strictness leads to organizational strength (Finke & Stark 1992; Iannaccone 1992, 1994). In particular, it has shown that strictness can function to screen out free riders, thereby raising average levels of commitment and participation within an organization. Like Kelley's book, however, the more recent work gives limited attention to the link between commitment and growth.

This essay tackles the subject of growth more directly. Building from the concepts of religious *resources* and religious *production*, it develops a theoretical

* *The first author's work on this article was supported in part by grants from the Lilly Endowment (#920370) and the University of Santa Clara. model in which "inputs" of time and money combine to "produce" new members. Growth statistics, both within and across denominations, demonstrate the empirical power of this approach. Although growth remains the central concern, we also examine the weaknesses of traditional measures of religious participation, offer suggestions for improvement, and demonstrate how our approach can enhance research on religious markets and denominational differences.

Our arguments owe an obvious debt to resource mobilization scholars, who repeatedly have emphasized that "study of the aggregation of resources (money and labor) is crucial to an understanding of social movement activity" (McCarthy & Zald 1977: 1216; see also McAdam, McCarthy & Zald 1988; McCarthy & Wolfson 1993). It is, however, from their general perspective rather than their specific propositions that we have borrowed most heavily. Compared to social movement organizations, mainstream denominations interact less with external constituencies and employ a much narrower range of resource-mobilizing strategies and technologies. Most of their energies go toward meeting the needs of a relatively small circle of members, who are in the language of McCarthy and Zald (1977:1215) the denominations' principal (goal accepting) "adherents," (resource providing) "constituents," and (benefit receiving) "beneficiaries."[1]

Modeling Growth

A religious organization cannot survive, much less grow, unless it obtains sufficient resources from the environment. Congregations need places to meet and people to lead them; church structures cost money to build and maintain; outreach, evangelism, and community service demands time and money; the activities of ministers, music directors, Sunday school teachers, and janitors never come free, even when supplied by volunteers[2] — a great many other examples could be cited.

Growth can occur only if there are *surplus* resources, such as time and money beyond the minimum required to maintain current operations and to compensate for depreciation in physical facilities and in membership lost to death or departure. Surplus funds permit a church to hire additional staff to design and direct programs of outreach that meet the social, physical, and spiritual needs of potential new members. Income spent on new or enhanced programs can also provide more and better services for current members and thereby increase retention. Assets used to expand and improve meeting facilities can help attract and accommodate additional members. Donations of members' time prove no less important than donations of money. People are naturally drawn to churches with an energetic membership ready to help with potlucks, teach Sunday school classes, serve on committees, organize worship services, sing in the choir, assist in soup kitchens and community outreach, and help other members with special needs. All these activities require volunteered time and effort, and all help to attract and retain members.

To avoid needless detail, it helps to lump resources under two broad headings, labor and capital, or their rough equivalents, time and money. People's time and effort are combined with purchased inputs (both physical

goods and hired services) to produce valued commodities. It follows that growth requires "inputs" of time and money and that greater inputs tend to facilitate growth and inhibit decline (other things remaining equal). Input requirements are not rigid, however, since there are many ways to accomplish almost any outcome, including growth. One congregation may rely heavily upon paid professionals, whereas another may get by with lay preachers and other volunteers. Religious organizations can thus *substitute* between time and money, although technological and normative constraints limit the degree of input substitutability (Oliver & Marwell 1992).

Standard economic production functions capture these features in a single symbolic expression:

$$G = F(L,K)$$

where G represents growth, L represents labor, K represents capital, and the mathematical function F specifies the relationship between inputs and outputs. Roughly speaking, this translates to

rowth = ti e + one

Stated more precisely, the expression asserts that growth is an increasing function of two substitutable inputs, labor and capital.[3]

The model abstracts from numerous details so as to keep the analysis simple and thus suitable for generating testable propositions. This is not to deny the possibility of other growth-related factors, such as the religion's content, the organization's commitment to growth and evangelism (Greer 1993; Hadaway 1993; Olson 1993; Royle 1993), the members' socioeconomic attributes, the presence of competing organizations (Finke & Stark 1992), and trends in the economic, social, and demographic environment (Hadaway & Roozen 1993; Hoge & Roozen 1979a). But clearly one is hard pressed to fully define, much less formally analyze and empirically test, a model of the form

growth = time + money + content + goals + member attributes
+ competition + trends + social environment + ...

The proposed model zeros in on two fundamental factors — time and money.[4] With it, we hope to demonstrate that the principles of resource mobilization provide an important, but often overlooked, step toward understanding church growth.[5]

At the national level, where environmental factors tend to randomize out and affect all denominations more or less equally, we expect resource variables to be among the most important determinants of denominational growth. At the local level, where social, economic, and demographic factors differ greatly from one community to the next, we expect that congregational growth will depend on a variety of factors but that resources will still prove important.

Measuring Resources

If growth depends on inputs of labor and capital, then one must attend to their measurement. Since virtually all the resources at the disposal of a religious organization originate with its members, we can obtain a fairly complete accounting simply by measuring the time and money that members devote to

religious activity. Ideally, one should also measure external support — from government agencies or foreign organizations — and the additional resources derived from financial investments, church-owned properties, and church-run businesses.

Unfortunately, the traditional social scientific measures of religious commitment and participation were not designed to provide this information. Consider, for example, the standard question asked in Gallup surveys for the past fifty years: "Did you, yourself, happen to attend church in the last seven days?" Using this item to assess the quantity and quality of a church's religious labor force is a bit like assessing hours of employment by asking people if they worked any time during the last week. We will know who worked, but not how much. The Gallup question provides no way to distinguish between minimally productive bench warmers and dedicated church servants.

To clarify the problem, consider the members who attend a worship service every week but never spend additional time in church or on church-related activities. It consumes substantial resources merely to produce a weekly worship service — a church building must be purchased (or rented) and maintained; someone must be paid or persuaded to conduct the service; others must help to provide music, plan the service, act as ushers, and so on. As long as the attenders contribute time and money equal to the total costs of providing the service, the organization breaks even. But if contributions fall below total costs, as can easily happen if most members do no more than attend, the organization runs a deficit on the very people that survey analysts routinely classify as "committed" members.

Members who show up only for worship services — even those who do so regularly — provide their church with little or no surplus labor. Such people scarcely count as members of the church's labor force, except insofar as their presence, singing, testimonials, and prayers enhance the worship experience of those around them. A church's survival thus hinges upon the number of members who devote time *above and beyond* standard worship services. Getting core members to show up for planning meetings, work days, choir practice, fellowship groups, and weekday Bible studies may prove much more important than getting casual members to attend more regularly.

This fact highlights a major shortcoming in the relatively detailed measure of church attendance used in the General Social Survey. Though it provides no fewer than ten response categories to the question "How often do you attend religious services?" only one of these categories describes more-than-weekly involvement. Active members must therefore choose between just two responses: "every week" and "several times a week." From the resource-mobilization perspective, this question needs many more high-end categories, not to mention additional questions on the hours and content of the individual's religious activities.

Despite these failings, the GSS data suffice to demonstrate how unevenly surplus labor varies across denominations. Figure 1 shows the percentage of people in various denominations who claim to attend religious services "several times a week."[6] (When working with national survey data, one must note that denominational affiliation reflects the respondents' self-identification rather than their official membership standing.) Within the "mainline" denominations

(Episcopal, Disciples, Lutheran, Methodist, Presbyterian, UCC, and Catholics) the fraction rarely exceeds 4%. In contrast, Southern Baptists weigh in at 12% and the so-called sects (Adventists, Jehovah's Witnesses, Mormons, and numerous fundamentalist/evangelical or pentecostal/charismatic groups) routinely score over 20%.[7] Among Jehovah's Witnesses, "several times a week" attenders make up a whopping 44% of the total.

Although more detailed data certainly would help, these figures leave no doubt that many of Kelley's "strict churches" have at their disposal vastly more volunteer labor than their mainline counterparts, per congregation and per capita. For all intents, there simply is no one minding the mainline store six days a week.

It is possible, of course, that the mainline makes up in dollars what it lacks in volunteer hours. Indeed, the proposed model of growth explicitly acknowledges substitution between labor and capital or time and money. Lay denominations, like the Mormons and the Jehovah's Witnesses, require substantial amounts of volunteered time to compensate for their lack of a paid clergy. Mainline denominations depend heavily upon paid and professional services, not merely in the pulpit but also in their administration, counseling, missionary societies, educational programs, music ministries, and building maintenance. Mainline members also average higher incomes and wage rates than their sectarian counterparts, so they have a rational incentive to pay for services (through contributions) that poorer people might produce with their own time.

Until quite recently, cross-denominational survey data on religious giving was largely unavailable.[8] However, in 1987 the General Social Survey began asking respondents "About how much do you contribute to your religion every year (not including school tuition)?" Though this question is not without problems (most notably, in failing to distinguish individual and household contributions), it provides considerable insight into denominational differences. Figure 2 graphs the average number of dollars contributed per (self-identified) member across various denominations. Once again, the mainline denominations place well below their sectarian counterparts. The contrast becomes even more striking when we measure *percentages* of income contributed to one's church. The Episcopalians, Disciples, Lutherans, Methodists, Presbyterians, UCC members, and Catholics all contribute less than 2% of their income. Southern Baptists, Adventists, fundamentalist/evangelicals, and pentecostal/charismatics contribute between 2% and 4%. And Mormons contribute more than 5%, nearly three times the mainline average.

Expert judgments provide a final approach to assessing resources. As an alternative to the survey-based measures of time and money, we asked sixteen scholars doing research on American religion to rate denominations according to their "demands on members' resources."[9] Specifically, we asked each scholar to consider: "Does the denomination expect members to devote a great deal of their time and/or money resources to the denomination's activities or causes?" They then assigned each of twenty-one Christian denominations a score from one to seven, with one representing the lightest demands and seven the heaviest. The level of agreement among the experts proved extraordinarily high. Interrater reliability of denominational scores (as measured by Cronbach's alpha[10]) was .98. The ratings also correlate strongly with the previously

described measures of weekday attendance and contributions (yielding a multiple correlation of .85 and simple correlations of .65 and .51, respectively). We return to these ratings in the next section.

Predicting Growth

Having used survey data to highlight the differences between American denominations in the resources available to them, we now use these same data to predict denominational growth. Stated differently, we test the time-and-money model of church growth using the only representative, cross-denominational sample currently available. If this simple model and crude explanatory variables account for a significant fraction of the observed variation in denominational growth, then one can be fairly confident that the resource-oriented approach merits further attention.

Predicting denominational growth with national survey data means working with sixteen cases in the 1970s and fifteen cases in the 1980s. The smaller denominations simply do not have adequate numbers of respondents in the GSS even after merging the survey responses from several years. Degrees of freedom thus limit the analysis to simple models with one or two independent variables.

Linear production functions provide the simplest approach to modeling growth as a function of time and money inputs:

$$G = a + b_l * L + b_k * K$$

Alternatively, one may employ an equally parsimonious loglinear specification (known as the "Cobb-Douglas" function) popular in economics and used extensively by Coleman (1990:667-949):

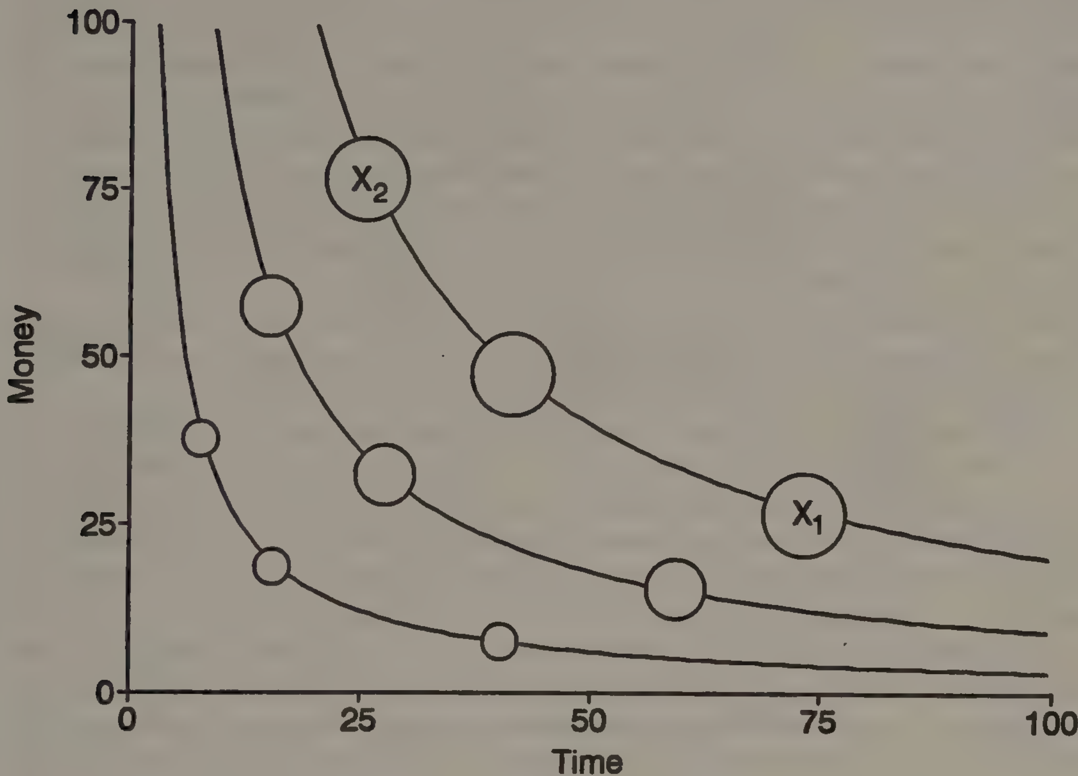
$$\log G = \alpha + \beta_l * \log L + \beta_k * \log K$$

Dividing all three variables by total membership, one obtains equations that describe growth *rates* as functions of time and money *per capita.* Ordinary least-squares regression can be used to estimate either set of equations. Although the linear specification appears somewhat simpler, resource mobilization scholars might nevertheless prefer the Cobb-Douglas specification, because it limits substitutability among inputs (and thereby maintains a substantive distinction between time and money). The Cobb-Douglas equation implies that each 1 *percent* increase in L leads to a β_L% increase in G, and each 1% increase in K leads to a β_K% increase in G. Hence, successive reductions in time can be offset only by progressively larger amounts of money, and no amount of money can take the place of all the time. In contrast, the additive structure of the linear model implies that each 1 *unit* increase in L inputs yields a b_L-unit increase in G. Time and money thus act as perfect substitutes, and each one-unit reduction in L can always be offset by exactly b_K/b_L more units of K.

Production functions can be depicted graphically using "isoquant" diagrams. Figure 3 displays an isoquant diagram corresponding to a Cobb-Douglas function. For each point in this diagram, such as the point labeled x_1, the horizontal and vertical coordinates (75,25) show the amount of time and money dedicated to production and the size of the circle surrounding the point depicts the resulting level of output. Since every combination of time and money yields *some* level of output, one may associate an output circle with every point in the diagram. However, the general shape of the production function may be inferred from just a few such points corresponding to a few levels of output.

In Figure 3 the innermost set of circles (closest to the origin of the time and money axes and thus using low inputs of time and money) depict input combinations that all yield the same, relatively low, output. The outermost set of circles depict input combinations that yield a high output. The intermediate circles denote input combinations that yield an intermediate level of output. The entire set of points that yield a particular level of output is called an isoquant. From the shape and position of the isoquants, one can infer the character of the underlying production process. In particular, one can draw inferences about *substitution* between inputs. In Figure 3, the points X_1 and X_2, depict two radically different methods of generating the same result, X_1 being much more *labor-intensive,* since it employs a much higher ratio of time to money.

FIGURE 3: Growth Isoquants



Turning to data, the *Yearbook of the American and Canadian Churches* (Jacquet & Jones 1992) provides annual reports of denominational membership (the membership figures having been supplied by the denominations themselves). The variable *growth 1980-90* measures a denomination's membership in 1990 divided by its membership in 1980 and so gives the proportional change over the last decade. The preceding section's discussion of religious resources explains why standard church attendance rates tend to overestimate the labor resources available to a denomination. Hence, we estimate *time* as the fraction of a denomination's members who attend religious services "several times a week." We estimate *money* by averaging the (inflation adjusted) amount of money that the members of each denomination reported in response to the GSS contribution question. Comparable measures may be defined and calculated for 1970 through 1980.[11]

The first two columns of Table 1 fit this simple, two-variable regression quite well, having an adjusted R^2 of .68 in the 1980s and .81 in the 1970s. Both sets of explanatory variables have the expected positive signs, and both are statistically significant. It would seem that religious resources do indeed "produce" membership growth in accordance with standard production models. Although these regressions employ a linear functional form and specific measures of time and money, the results prove quite robust. The logarithmic

counterparts of all these equations yield qualitatively similar results, as do regressions using alternative measures of attendance and contributions.[12]

Figure 4 graphs the relationship between attendance, contributions, and church growth for the twenty denominations. Following the style of Figure 3, the horizontal and vertical axes measure a denomination's time and money inputs and the size of a denomination's circle depicts its growth rate. The small circles clustered in the lower left of the diagram represent the mainline denominations: low inputs and low to negative growth (averaging between zero and -15%). Most of the conservative denominations and sects occupy the middle of the diagram: their relatively high inputs yield moderate to high rates of growth (averaging between 10 and 20%). Two highly sectarian denominations — the Mormons and Jehovah's Witnesses — stand out in their exceptionally high rates of growth (over 50%) and high levels of attendance or contributions. Jehovah's Witnesses distinguish themselves as by far the most labor-intensive denomination; Mormonism is extraordinarily money-intensive.

The third column of Table 1 shows that expert judgments about demands on denominational resource predict 91% of the variation in denominational growth rates in the 1980s and 74% in the 1970s, more than the survey-based time and money measures combined.[13] Figure 5, which graphs the relationship between resource demands and growth in the 1980s, is nothing short of amazing. In contrast, columns 4 through 7 of Table 1 show that standard demographic variables do a much poorer job of predicting growth. Other demographic controls, such as race, sex ratios, and percentage married do worse yet. The small number of observations makes it impossible to estimate resource regressions while simultaneously controlling for demographic variables. But in stepwise regressions, resource demands and time variables consistently entered before demographic variables, and their *t*-statistics did not decline appreciably after controlling for individual demographic variables.[14]

The basic message is clear. In each of the past two decades, the decline of the liberal/mainline denominations and the growth of their more strict/conservative counterparts can be modeled largely in terms of the radically different amounts of time and money that they demand and receive from members. At this level of analysis, denominational dynamics prove surprisingly straightforward.

From Denominations to Congregations

Although the discussion so far has centered on denominations, there is nothing in the resource model that requires its application to aggregate levels. On the contrary, the model's growth-producing processes tend to operate at the level of individual congregations as sermons are preached, classes are taught, chapels are maintained, and music is performed. Hence resources should also predict the growth of congregations. If the model fails at the congregational level, one might reasonably question whether the denominational findings are artifacts of spurious correlation and the small number of observations.

We have, in fact, found two distinct congregational data sets suitable for analysis. Both permit tests of the effects of the resource variables while also

[a] Sources: General Social Surveys, 1972-1990; Yearbook of American and Canadian Churches, 1970-1992; and a survey of experts.

Beta values are in plane text; absolute *t* statistics are in parentheses.

Variable definitions: All for the following variables are measured or aggregated at the level of the denomination.

Yearbook data: growth 1980-90 = 1990 membership divided by 1980 membership; growth 1970-80 = 1980 membership divided by 1970 membership; money70 = contributions per member.

Expert ratings: demands = 7-point, additive scale.

GSS data: time80, time70 = percent attending "several times per week"; money80 = (inflation adjusted) average contribution, 1987-1989; income80, income70 = (inflation adjusted) real income; educ80, educ70 = average years of education; age80 = average age; nchild70 = average number of children.

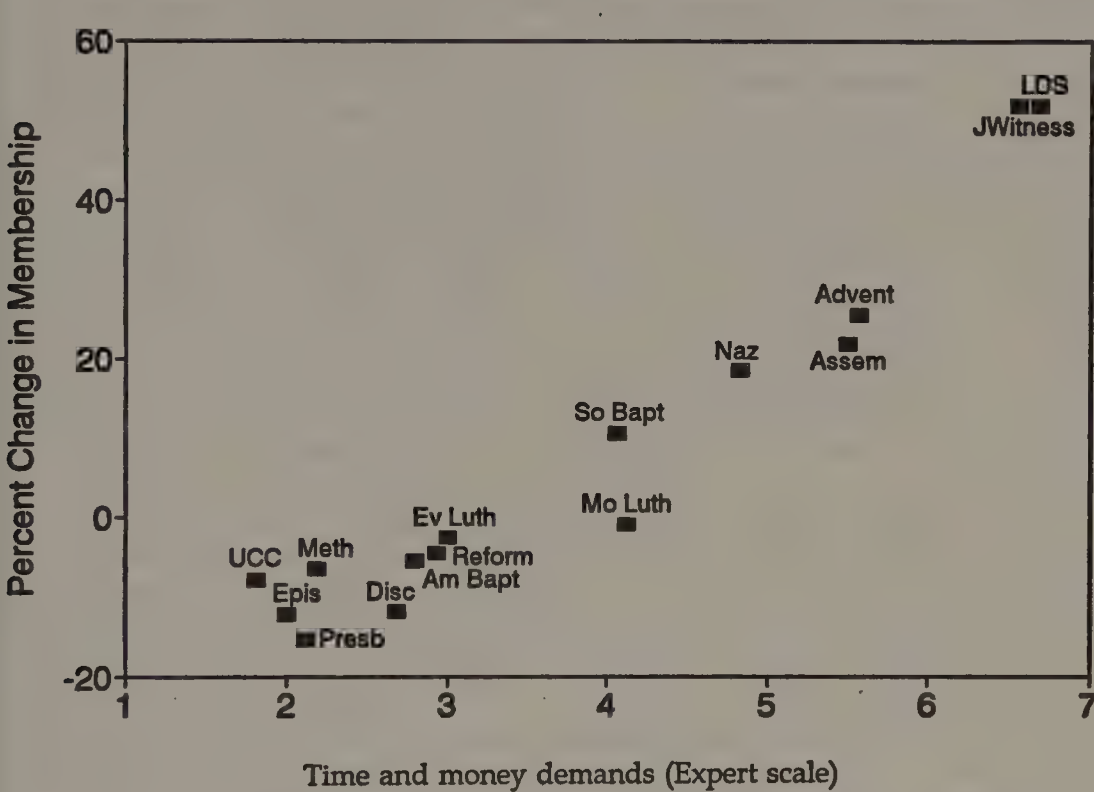
controlling for the effects of variables other than resources, and both confirm the importance of resources.

The first set, which covers about 400 Disciples of Christ congregations, was assembled and analyzed by Meyers and Olson (1991). The data include congregational membership from 1979 to 1983 and a variety of other congregational attributes measured in 1979. Using regression techniques and the variables at hand, Meyers and Olson sought to identify the statistical predictors of church membership growth. They concluded that "high levels of member involvement (as reflected in higher levels of per capita giving and higher rates of participation in church school) *precede* increases in church size" (509). To state the matter bluntly: time and money predict growth better than virtually any other variables.

Table 2 reprints Meyers and Olson's key regression. A few points deserve emphasis. First, the dependent variable is the rate of change in a congregation's membership from 1978 through 1983. Second, the full set of independent variables is quite diverse, and all of them predate the period over which growth is measured. Third, two of the three strongest predictors (as measured by t statistics and betas) turn out to be expenditures per member and frequency of church school attendance per member. The expenditure variable constitutes the only available measure of money inputs, since individual giving was not part of the data set. Church school attendance constitutes the only available proxy for time inputs. It gives the average number of children and adults attending

FIGURE 5: 1980-1990 Membership Growth versus Resource Demands



Sunday school and Bible studies and so provides a measure of participation beyond the Sunday worship service. As can be seen in Table 2, several other congregational attributes prove statistically significant, but none except race is as powerful as these two resource-oriented measures. For further details, see Meyers and Olson (1991).

Our second set of results come from a much larger study conducted by the United Church of Christ, a liberal mainline denomination that has been losing members since the 1960s. The data cover nearly a thousand UCC churches and include both congregational and individual responses. The individual-level data were collected as part of a 1975-78 "Church Membership Inventory" in which each participating church distributed a 43-item questionnaire to all persons in attendance during a regular worship service. According to the project director, William McKinney, virtually everyone present completed the questionnaire, yielding a total of more than 70,000 responses and an average of 77 respondents per church. We used these individual responses to compute aggregate values (such as the respondents' average age and income) for each church. We also merged in data from the UCC's 1973-81 yearbooks, which include official membership and financial statistics for each church. Finally, we obtained decennial census statistics for the communities surrounding each church.

As in the denominational regressions, growth is defined as the number of members in one period (1981) divided by the number of members in an earlier period (1977). Since nearly all the participating churches completed their

Beta values are in plane text; absolute *t* statistics are in parentheses.
Variable definitions:
growth = percentage growth in congregation, 1979-1983;
sunday_school = proportion of members who were in church school in 1979;
expense = per capita congregational expenses in 1979;
race = indicator variable for predominantly white membership;
elite = proximity to a Disciples college or seminary;
non_disciple = the proportion of the last 12 years during which the congregation was led by person(s) with a degree from a mainline, disciple-related, but not disciple-owned seminary;
non_seminary = proportion of years led by person(s) with no seminary training.

* $p < .05$ ** $p < .01$ *** $p < .001$

questionnaires before the end of 1977, this measure of growth postdates the other congregational measures, and thus cannot have influenced the independent variables of our regressions.

Unfortunately, membership data for congregations are notoriously "noisy" because the rolls are cleaned of inactive members only irregularly.[15] This lowers the R^2 values obtained in regressions, but it also means that only the strongest independent variables appear as significant predictors of congregational growth. If resource measures predict growth in even these noisy data, one can be fairly confident that they really do matter.

From the UCC yearbook statistics we have computed two measures of monetary resources: per capita contributions and per capita church expenses. (The yearbook statistics exclude bequests, endowments, and income from other sources, such as building rental and product sales.) These data reflect the actual money received by the church, and so avoid biases due to mistaken or exaggerated reporting.

We have already noted that church attendance provides only a crude measure of the time that members devote to their churches. Sadly, the UCC data do not provide a very good measure even of attendance. The average attendance reported by questionnaire respondents contains a strong upward bias, in that regular church attenders were much more likely to be in church when the questionnaire was distributed. Hence, we have estimated attendance as the number of questionnaire respondents divided by the same year's number of official members.[16] The number of questionnaires provides a reasonable estimate of attendance on a typical Sunday, since they were distributed to and completed by nearly everyone in attendance.

The first column of Table 3 contains the basic, linear regression results. As in the denominational data set, contributions and attendance significantly predict growth. UCC congregations with higher per capita contributions and higher attendance (relative to membership) manifest significantly more membership growth in the four years following the survey. In other words, contributions and attendance act as leading indicators of congregational growth. The regression's adjusted R^2 is low, around 6%, though it is hard to imagine a good fit emerging from such noisy measures of growth and such crude measures of participation.[17] There are, moreover, numerous environmental factors that can influence growth at the local level.

The second and third regressions, in columns 2 and 3 of Table 3, give these other factors a chance to compete with the resource variables. Though cognizant of the dangers of statistical fishing expeditions (Leamer 1978), we nevertheless used one here simply to show that the estimated impact of resources is not an artifact of omitted variables. Column two reports the results obtained in a stepwise search over dozens of nonresource variables from the questionnaire, census, and yearbook data. All variables are measured or averaged at the level of the congregation.

Only three nonresource variables proved strongly related to congregational growth. As we have seen in previous research (e.g., Hoge & Roozen 1979a), changes in the surrounding community's population significantly affect congregational membership. Our results also echoed previous research in that population transiency (proxied in our data by the proportion of questionnaire respondents renting an apartment) proved a strong negative predictor of future growth. In the language of the production model, transiency probably causes the membership to "depreciate" faster. Following Olson (1987, 1989), we find evidence that a very high level of average membership tenure also inhibits growth. In churches filled with long-time attenders, current members have many friends, but newcomers find it difficult to form fellowship ties and so perceive the churches as "closed" and "cliquish." In the logarithmic, but not the linear, versions of the regressions, membership growth before 1977 correlates negatively with subsequent growth (suggesting that growth in one period tends

[a] Beta values are in plain text; absolute t statistics are in parentheses.
Variable definitions: growth = 1981 membership/1977 membership;
contributions = per capita contributions;
attendance = number of questionnaire respondents/1977 membership;
renters = share of members living in rented housing;
yrs_attend = average years attending this congregation;
age = average age of respondents;
growth7377 = membership in 1977/membership in 1973;
members77 = congregation membership in 1977
pop_growth = community population in 1980/community population in 1970.
All variables are measured or aggregated at the level of the individual congregation.

* $p < .05$ ** $p < .01$ *** $p < .001$

to dissipate the resources needed to facilitate future growth — see Meyers & Olson 1991). Finally, larger congregations tend to have lower growth rates, but this effect turns insignificant after taking account of contributions and attendance (suggesting that insofar as initial size may affect subsequent growth, it does so through its impact on participation levels). Altogether, the nonresource measures account for about 9.5% of the variance in growth. Variables dropped for lack of statistical significance were the demographic characteristics of

individual church attenders (average age, average income, average education, average occupational prestige, average number of children living at home, etc.), homogeneity-diversity of church attenders (standard deviation of ages, incomes, education, etc.), percentage distribution of the church's overall budget to different categories (capital expenditures, money sent to the denomination, and money sent to nondenominational organizations like World Vision or local charities), and attenders' average satisfaction with nine aspects of church life.[18]

Comparing columns 1 and 2, we see that the two *preselected* resource variables predict nearly as well as all other statistically significant variables (searched from among several dozen variables) combined.[19] Comparing columns 1 and 3, we see that the statistical influence of contributions and attendance remains strong even after including the other variables. And columns 2 and 3 show that resources increase total explained variance even after including all other significant predictors. In unconstrained stepwise regressions, contributions and attendance entered before any variable except population growth. The logarithmic counterparts of all three regressions yield qualitatively similar results.[20]

In short, resources really do matter. Whether we study entire denominations or individual congregations, time and money stand out as statistically significant determinants of growth. The theoretical model survives empirical scrutiny — a result with general implications for organizational analysis and specific applications to religious research.

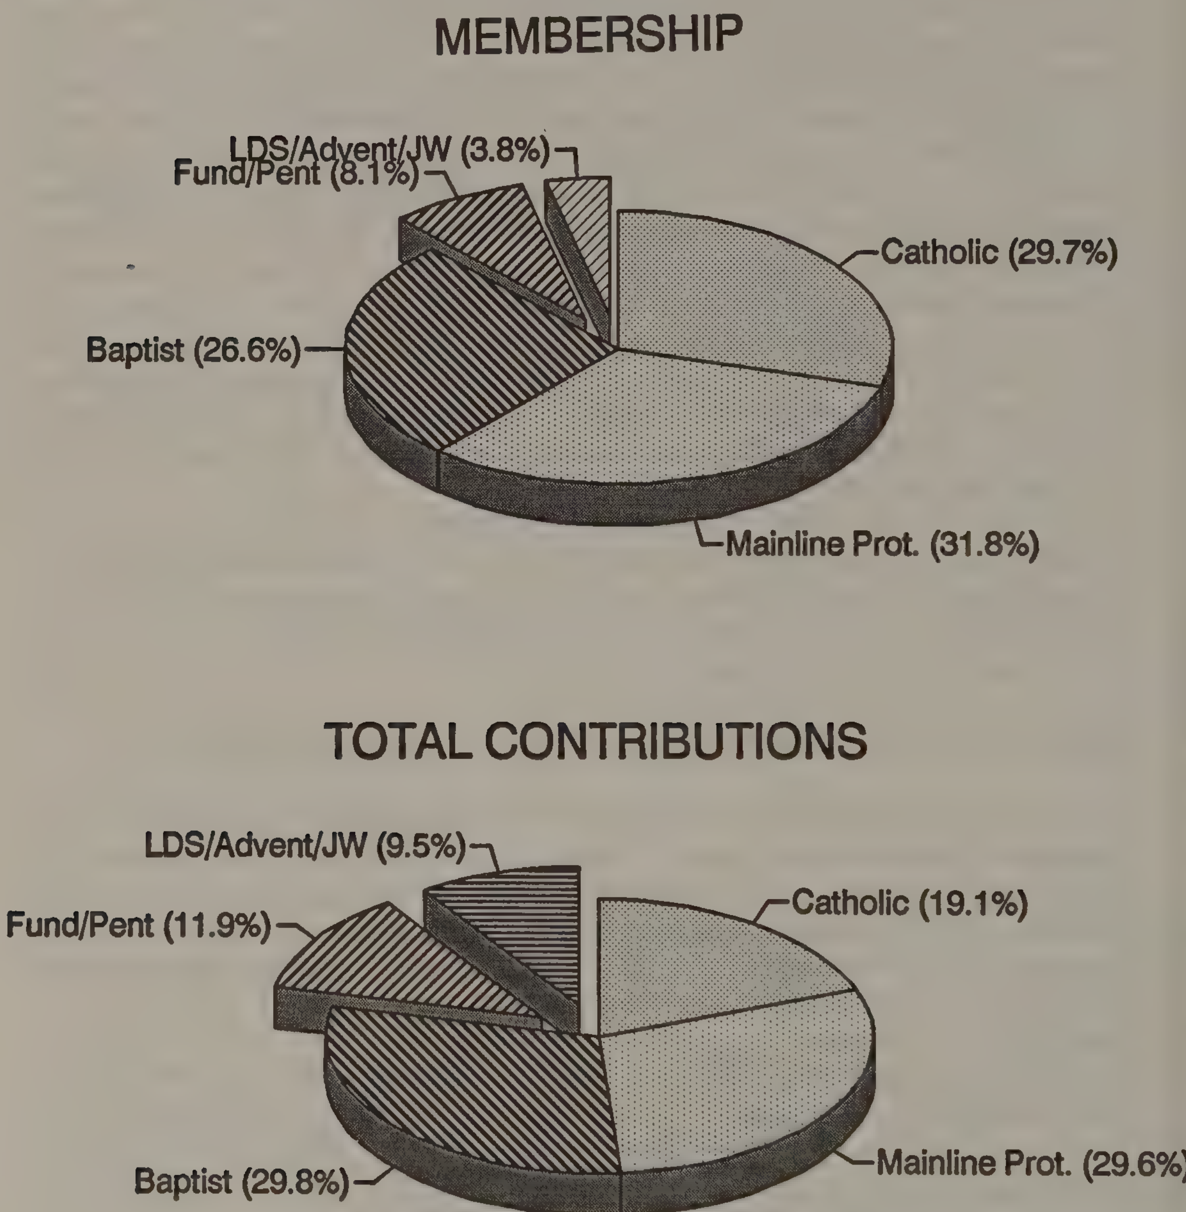
Extensions: "Resourceful" Thinking about Religious Market Shares

Having demonstrated that resources affect church growth at both national and local levels, we turn briefly to a related issue — assessing the relative sizes of denominations. Our goal is twofold: to further demonstrate the value of resource-oriented thinking and to provide some specific insights that call for a major reevaluation of the relative size and strength of American denominations and a reassessment of some longstanding notions about the difference between Catholics and Protestants.

One hears much talk these days about "religious markets." Indeed, Steven Warner (1993) recently argued that the market-oriented approach has attained the status of a "new paradigm" in the sociology of religion and is well on its way toward displacing the traditional secularization paradigm. Even so, scholars have not given much thought to measuring the size and composition of religious markets.

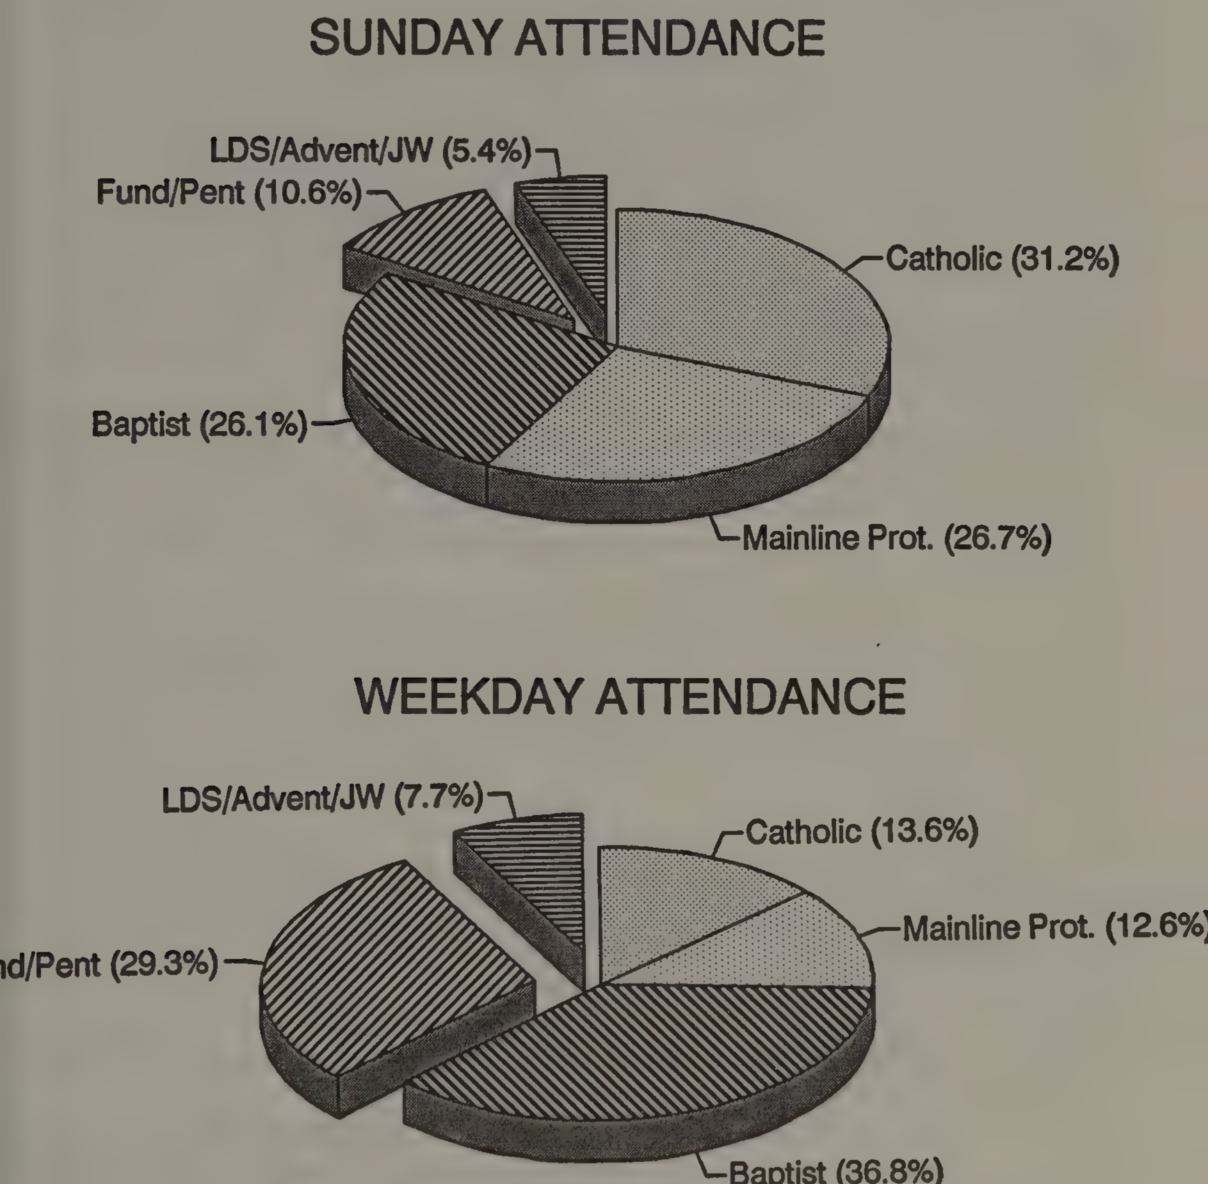
In standard markets, such as the market for automobiles, industry analysts routinely calculate market shares in both dollar and "unit" sales. Religious research would benefit greatly from an analogous distinction. Traditional scholarship has, more or less unconsciously, based its conclusions on *numbers* of official or self-identified members. Membership numbers have their uses, but they often prove misleading when comparing groups whose members manifest significantly different rates of participation and commitment. Dollar contributions provide an alternative measure of market share, and probably a more useful measure of market power. The total amount of time devoted to religious activities provides yet another measure.

FIGURE 6: Alternative Measures of Market Share[a]



The relative market shares of major denominations change dramatically with the measure we employ. For example, the Methodists and Southern Baptists have fairly similar numbers of self-identified members, but the contributions of the latter are nearly *twice* those of the former. Measured in dollar contributions, the Mormon church is virtually the same size as the Methodists, despite a total membership that is one-seventh their size. The Jehovah's Witnesses have more members attending "several times per week" than are found among the Episcopalians, UCC, and Presbyterians combined! (The mainline denominations' share of the financial pie shrinks further still if

FIGURE 6: Alternative Measures of Market Share[a] (Continued)



[a] Source: General Social Surveys, 1984-90
Fund/Pent = Fundamentalist and Pentecostal groups
LDS/Advent/JW = Mormons, Adventists, and Jehovah's Witnesses

one subtracts monies spent on clergy and staff before making comparisons with groups like the Jehovah's Witnesses and Mormons whose lay clergy guarantees that most contributions go to missionary work, building construction and maintenance, and other church programs.)

For an overview of these differences, consider the four pie charts in Figure 6. The charts provide four views of the market shares of Christian denominations — membership, Sunday attendance, weekday attendance, and total contributions. All data come from the 1984-90 *General Social Surveys,* and the only omitted groups are "nondenominational" Protestants and a handful of very small, hard-to-classify denominations. In the market for (self-identified) members, Catholics, non-Baptist mainline Protestants, and Baptists each have approximately 30% shares, whereas the sects (Fundamentalists, Pentecostals, Mormons, and others) have a mere 12%. Measured in terms of Sunday church attendance, the mainline shrinks a bit and the sects rise to 16%. Measured in terms of dollar contributions, the sects rise to more than 20%, and Catholics shrink to less than 20%. In other words, despite having three times the population, Catholicism's share of the market for religious contributions is no larger than that of America's sectarian "fringe." The sectarian share is all the more striking given that their members average relatively low incomes.

The most dramatic result concerns weekday attendance, defined here as the number of GSS respondents claiming to attend religious services "several times a week." By this measure, sectarians constitute more than a third of the market, as much as the Baptists, and substantially more than the Catholics and the mainline Protestants put together.

Data from Canada's *General Social Survey* prove that the preceding results are not unique to the U.S. The 1986 Canadian GSS asked people whether they had attended church any time Monday through Friday of the past week. Figure 7 shows how the response to this question differs from the response to the more standard membership question. Although the Canadian survey's denominational breakdown is less detailed than that obtained from the U.S. data, the basic pattern is the same. Conservative Protestants (Baptists and Evangelicals) make up only 12.8% of the market for members — less than half the size the more liberal Protestant denominations (Anglican, Lutheran, UCC, and Presbyterian) and less than one third the size of the Roman Catholic membership. But their share of the weekday market is 38%, just shy of the Catholic share and more than twice the liberal Protestants' share. Hence, in Canada as in the U.S., simple measures of membership or affiliation provide a biased view of the religious marketplace.

Why focus on the relatively small number of people who attend church "Monday through Friday" or "several times per week"? Because it is precisely this core of very committed members who provide the surplus labor that makes church growth possible. In like manner, future research should focus attention on the surplus dollars available for expansion, evangelism, and renewal, a surplus left after subtracting the portion of contributions that merely cover basic operating costs. The preliminary evidence (of Figures 2 and 6) leave little doubt that sects command a disproportionate share also of this pie.

FIGURE 7: Market Shares in Canada[a]

Conclusions

Why do some religious organizations grow while others decline? The complete answer is, no doubt, exceedingly complex. Nevertheless, both theory and data suggest a strikingly simple partial answer. Growth requires resources. It is a "product" derived from "inputs" of labor and capital, which is to say time and money. Hence, religious organizations with high average rates of participation tend to grow, and religious organizations with low average rates of participation tend to decline.

Empirical research on church growth has often emphasized every factor *except* attendance and contributions — theology, polity, demographics, attitudes, population growth, and the state of the economy. Our analysis suggests that the impact of these variables is dwarfed by that of time and money. A shift in scholarly focus would seem to be in order. Resources deserve more attention and much more careful measurement. Previous research has tended to view church attendance as a simple attribute, comparable to an individual's beliefs or demographic characteristics. We have argued that church attendance is merely the tip of the resource iceberg. Regular attendance is well and fine, but not to be confused with the surplus resources that an organization needs to thrive. Researchers need to look closer, so that it will be possible to speak not only of the amount of time that members devote to an organization but also the particular activities they have undertaken. Previous research on contributions is even more limited than the work on time; indeed it is almost nonexistent. Our results underscore the need to devote much more attention to the measurement and analysis of religious giving.

In the end, however, resource-oriented research complements, rather than replaces, more traditional approaches. It especially complements existing research on the determinants of denominational strength and success. The theoretical link from organizational strictness to organizational strength has received a great deal of attention in recent years. The empirical relationship between strictness and growth has been observed for more than two decades, but causal explanations have been largely lacking. Resources provide a critical bridge, helping us see how a strict organization's strength leads (via high rates of participation) to growth.

Notes

1. Many "New Religious Movements" are exceptions to this rule. Bromley (1985), Lofland (1979), and others have effectively employed standard resource mobilization theory to study the financial strategies of the Unification Church and other NRMs (see Robbins 1988:127-33).

2. When volunteers provide "free" services, they bear an opportunity cost equal to the value of their sacrificed time and energy. The church also bears a cost, since the person who volunteers to do one job cannot simultaneously do other church jobs.

3. Strictly speaking, a standard economic growth model would look more like the following:

$$dQ/dt = F(L_t, K_t) - \delta \cdot Q_t$$

where Q_t represents quantity of members at time t, δ represents the rate at which membership "depreciates" or declines (due to deaths, dropouts, mobility, depreciation of facilities, and the like) in the absence of continuing investment, the derivative dQ/dt represents the

current rate of membership growth, and L_t and K_t represent the flows of labor and capital invested in continued growth.

4. It is, of course, possible to collect census, survey, and church record data on hundreds of factors that might fall into one or more of the preceding headings, and then search through massive correlation matrices and stepwise regressions for items that best predict growth. Most empirical studies of congregational growth do just that (Hoge and Roozen 1979a; Roozen and Hadaway 1993). Such methods have value in exploratory research, but they do not constitute hypothesis testing, and they do not take the place of formal models. For more on this subject, see Iannaccone (1996).

5. The model does not rule out the impact of the other factors noted above; it merely assumes that they operate indirectly. Theology, socioeconomic attributes, commitment, goals, and the social environment can still influence membership retention and recruitment, but they must do so *through* resources. For example, a member's personal feelings of commitment can affect growth, but only insofar as these feelings give rise to concrete actions — reaching out to people in need, serving on church committees, testifying publicly to one's faith, and contributing to the building fund. The model thus restricts the mechanism by which other factors determine growth.

6. The percentages in Figure 1 are undoubtedly inflated, since survey respondents tend to overstate their actual rates of church attendance (Hadaway, Marler & Chaves 1993). However, given the widespread nature of this bias, the denominational comparisons almost certainly remain valid.

7. The Mormon rate of 6.4% is misleadingly low because beginning around 1979 the LDS Church consolidated its meeting schedule, moving several types of services, which previously met throughout the week, to Sundays. Hence, although many Mormons now "attend religious services" only once each week, this attendance includes three different meetings totaling about three hours. Moreover, Mormons routinely devote substantial additional time to their religion: visiting other members ("home teaching"), serving on missions, worshiping in the home ("family home evening"), attending a variety of church-sponsored events ("Firesides," dances, and recreational events), and serving the church in administrative, teaching, and other capacities. None of this activity is measured by standard church attendance survey questions.

8. The major exceptions are Stark and Glock's (1968) survey of San Francisco Bay Area church members and a national population survey conducted by the Yankelovich organization for the Independent Sector in 1984.

9. This was only one of nine dimensions along which the experts rated the denominations. The other eight dimensions repeated questions from a study conducted by Dean Hoge (Hoge & Roozen 1979a:179-97, 1979b:E1-E14). The other questions concern the denominations' "emphasis on distinctive life style and morality," "attitude toward pluralism of beliefs among members," "theological conservatism or liberalism," "strength of ethnic identity," "attitudes toward ecumenism," "centralized or congregational polity," "emphasis on local and community evangelism," and "involvement in social action." In all cases, our experts' average ratings correlated almost perfectly ($r > .92$) with those produced by Hoge's experts, suggesting extraordinary stability in the (perceived) character of denominations over the past fifteen years.

10. Typical survey-based scales are formed by summing an individual respondent's scores on several survey items. Cronbach's alpha then provides a measure of inter-item correlation across the sample of respondents. The present scale is formed by summing the responses of 16 experts. Hence, each expert acts as a different "item" or measure of the underlying characteristic (resource demands), and each denomination acts as a separate case. In this context, Cronbach's alpha provides an index of correlation among the experts and thus is a measure of interrater reliability. The presumed statistical model is $s_{ij} = t_j + e_{ij}$, where s_{ij} denotes the ith expert's distinctiveness score for the jth denomination, t_j denotes the jth denomination's true distinctiveness level, and e_{ij} denotes the (random) error in the ith expert's judgment on the jth denomination.

11. The 1970s money data come from denominational figures reported in the *Yearbook*. Ideally, one would like to define and measure all variables on a single, consistent membership criterion. In practice, population surveys assign respondents to denominations from their stated religious preference or identification, whereas denominations report membership figures (and

thus per capita contributions) on the basis of official institutional membership, the criteria for which vary significantly from one denomination to the next. Fortunately, these differences become less problematic when comparing growth rates over time. The effects of "loose" or "strict" membership criteria tend to wash out, because they inflate (or deflate) a denomination's membership figures consistently year after year. Population surveys attain a comparable consistency, since they apply a single, self-identification-based membership criterion across all denominations.

12. The logarithmic regression results corresponding to the second and first rows of Table 1:

$$\log(\text{growth7080}) = \underset{(3.888)^{**}}{.631} \cdot \log(\text{time70}) + \underset{(1.564)}{.304} \cdot \log(\text{money70}) \qquad \text{Adjusted } R^2 = .739$$

$$\log(\text{growth8090}) = \underset{(2.856)^{*}}{.603} \cdot \log(\text{time80}) + \underset{(1.265)}{.267} \cdot \log(\text{money80}) \qquad \text{Adjusted } R^2 = .382$$

13. The experts tended to produce very similar rankings when asked to rate denominations with regard to other attributes — lifestyle distinctiveness, belief strictness, theological conservatism, ecumenism, evangelistic emphasis, and involvement in social action (but not strength of ethnic identity or centralized polity). This might reflect a tendency to oversimplify and implicitly assume that most denominational attributes covary along a single underlying dimension. It also underscores the potential for spurious correlation when working with a small number of observations. On the other hand, there *are* strong theoretical reasons for expecting many of these attributes to cluster (Iannaccone 1994; Kelley [1972] 1986).

14. Simultaneously regressing growth onto resource demands and demographic controls yields:

$$\text{grow7080} = \underset{(4.10)^{***}}{.963} \cdot \text{demands} + \underset{(0.21)}{.066} \cdot \text{income70} - \underset{(0.07)}{.192} \cdot \text{educ70} - \underset{(0.88)}{.184} \cdot \text{nchild} \qquad \text{Adjusted } R^2 = .719$$

$$\text{grow8090} = \underset{(8.04)^{***}}{.985} \cdot \text{demands} - \underset{(1.12)}{.232} \cdot \text{income80} + \underset{(1.75)}{.292} \cdot \text{educ80} + \underset{(0.01)}{.001} \cdot \text{age} \qquad \text{Adjusted } R^2 = .915$$

The impact of demographic controls is equally small when regressing growth onto attendance and contributions. As noted in the text, other controls have even less impact. This includes controls for each denomination's total size and average congregational size. It also includes controls for the regional distribution of the denomination's membership (percentage located in the West, South, and East) and a "regional growth index" (formed as a weighted average of regional population growth rates multiplied by the fraction of a denomination's membership located in that region). For more on the definition of these controls, see Hoge & Roozen (1979b:E1-14).

15. Most UCC conferences set a minimum contribution that each congregation is supposed to send to the denomination. This amount is based on the number of members reported to the denomination, which encourages congregations to remove inactive members. Even so, actual year-to-year changes in reported membership suggest that roll cleaning occurs very erratically.

16. We also attempted to create an alternative measure, based on a weighted average of the respondents' self-reported attendance rates — the individual weights being proportional to the *inverse* of the individual respondent's attendance rate. However, this proved quite unstable, since respondents with very low attendance rates received extremely large weights.

17. The results printed in Table 3 provide our most conservative estimate of the impact of contributions and resources, based on a subsample of the data that excludes 49 extreme cases. The (more impressive looking) results from the entire sample are:

$$\text{growth} = \underset{(6.75)^{***}}{.218} \cdot \text{contrib} + \underset{(8.19)^{***}}{.265} \cdot \text{attend} \qquad \text{Adjusted } R^2 = .148$$

$$\text{growth} = \underset{(2.07)^{*}}{-.070} \cdot \text{renters} \underset{(5.45)^{***}}{-.200} \cdot \text{yrs\_attend} - \underset{(1.88)}{.061} \cdot \text{members77}$$

$$-.012 \cdot \text{grow7377} + .106 \cdot \text{pop\_growth}$$
$$(0.37)^{*} \quad (2.94)^{**} \qquad \text{Adjusted-}R^2 = .074$$

$$\text{growth} = .244 \cdot \text{contrib} + .223 \cdot \text{attend}$$
$$(7.01)^{***} \quad (6.48)^{***}$$
$$-.109 \cdot \text{renters} - .134 \cdot \text{yrs\_attend} + .042 \cdot \text{members77}$$
$$(3.36)^{***} \quad (3.80)^{***} \quad (1.27)$$
$$.052 \cdot \text{grow7377} + .006 \cdot \text{pop\_growth}$$
$$(1.60) \quad (0.16) \qquad \text{Adjusted } R^2 = .178$$

18. Two sets of questionnaire items ask about church satisfaction. The first set asks respondents whether they are seeking help in nine areas of their lives; the second set asks how helpful the church actually has "been to you in the following areas of your life?" The nine areas were (1) be aware of the needs of others in my community, (2) build good moral foundations for my personal life, (3) find meaning for my personal existence, (4) raise my children properly, (5) know of God's care and love for me, (6) meet my personal problems of anxiety, conflict, etc., (7) strengthen my faith and religious devotion, (8) understand my daily work as Christian vocation, (9) work for justice in my community and my world.

19. When comparing the two sets of variables, one must recall that searches tend to inflate R^2 and overstate significance levels. In other words, it is unlikely that an alternative theory would have predicted, *in advance*, the two or three variables that happen to outpredict resources in this data set. It is also unlikely that the *same* two or three variables will outperform resources in a different data set.

20. The logarithmic regressions corresponding to the linear regressions in Table 3 are as follows:

$$\log(\text{growth}) = .154 \cdot \log(\text{contrib}) + .159 \cdot \log(\text{attend})$$
$$(4.69)^{***} \quad (4.84)^{***} \qquad \text{Adjusted } R^2 = .054$$

$$\log(\text{growth}) = -.121 \cdot \text{renters} - .178 \cdot \text{yrs\_attend}$$
$$(3.91)^{***} \quad (5.48)^{***}$$
$$-.066 \cdot \log(\text{grow7377}) + .134 \cdot \log(\text{pop\_growth})$$
$$(2.20)^{*} \quad (4.13)^{***} \qquad \text{Adjusted } R^2 = .078$$

$$\log(\text{growth}) = .128 \cdot \log(\text{contrib}) + .128 \cdot \log(\text{attend})$$
$$(3.89)^{***} \quad (3.78)^{***}$$
$$-.131 \cdot \text{renters} - .138 \cdot \text{yrs\_attend}$$
$$(3.87)^{***} \quad (3.78)^{***}$$
$$-.014 \cdot \log(\text{grow7377}) + .131 \log(\text{pop\_growth})$$
$$(0.41)^{*} \quad (3.66)^{***} \qquad \text{Adjusted } R^2 = .117$$

The significance levels of the coefficients in these equations mirror those of their linear counterparts. The logarithmic specification might nevertheless be more appropriate given the highly skewed rates of congregational growth and per capita giving found in the UCC data. Log transformations make the distributions of both these variables much more nearly normal.

Book Reviews

Japanese Auto Transplants in the Heartland: Corporatism and Community.
By Robert Perrucci. Aldine de Gruyter, 1994. 186 pp. Cloth, $37.95; paper, $18.95.

Reviewer: CHOONG SOON KIM, *University of Tennessee at Martin*

In this case study, Perrucci delineates portraits of six Japanese automobile transplants (Honda, Nissan, Mazda, Diamond Star, Toyota, and Subaru-Isuzu) in the Midwest corridor, including the states of Michigan, Illinois, Indiana, Ohio, Kentucky, and Tennessee. After examining "the actions of corporations, political officials, workers, environmentalists, and business people involved in the transplant project as reflections of opposed interests of contending social groups and classes," he concludes that "economic development policies and programs in a local community are shaped by the competing interests of social groups and classes." This book is essentially a study in political economy.

Under the theoretical orientation of so-called embedded corporatism, the author searches for answers to four major questions: Why did the transplants locate in the Midwest corridor? How is a state's economic incentive package presented to various interest groups and the public? How will U.S. workers respond to new approaches to developing worker commitment and to the new strategies of changing the organization of work at the point of production? What will be the long-term impact of the auto transplants on the local and regional social and economic structure?

In an appendix, Perrucci explains his various data-gathering techniques. His inclusive method makes this book a rich source of information and makes it more likely that the volume will attract a wide readership outside the boundaries of sociological circles. One of its strengths is "thick description" — to borrow the words of Clifford Geertz — that relates the voices of Americans and Japanese expatriates involved in the transplants. The author presents not only an aggregation of statistics and managerial strategies but also a story of a concrete nexus of social relations in a particular industrial setting of the Midwest corridor.

As an anthropologist, however, I sometimes had the impression that Perrucci's interest in generalization tended to override local realities. For example, his use of regression analyses to determine the characteristics associated with the location decisions of the transplants is unconvincing. The outcome of his regression analyses appears to be at odds with the case of Tennessee as I have observed it. Perhaps it may be advisable to repeat Francis L.K. Hsu's warning: "Some of our scientific investigations are not unlike counting, classifying and 'computerizing' pebbles on the beach to determine the causes of rising and ebbing of tides."

Nevertheless, the book's merits and contributions are many, and its shortcomings few. It is one of the best works written on the subject and a pleasure to read. I strongly recommend it for advanced undergraduate and graduate students, faculty, and professionals and policymakers at the state level who are involved in foreign direct investment. The book also provides a good up-to-date bibliography.

Places on the Margin.
By Rob Shields. Routledge, 1991. 334 pp. Cloth, $52.50; paper, $17.95.

Reviewer: ROBERT E. PARKER, *University of Nevada, Las Vegas*

This book is intended to serve as a contribution to urbanists, sociologists, anthropologists, and human geographers attempting to explicate the connections between space and culture. Shields is concerned with the everyday use of stereotypes and images of places and spaces, emphasizing that place-names are not simply locations but areas that incorporate a complex set of meanings and images that create social reality. To illustrate his argument, he examines marginal places, areas distinctive in their cultural distance from the norms of the larger society (geographic marginality is less central). The author believes that such places encourage a keener appreciation of a society's core values.

The first part of the book includes an introduction and a theoretical chapter. Shields reveals his ambition in the former when he states his plans to "demonstrate the importance of spatial concepts and categories . . . for the whole way in which we go about thinking about our world." Further, while he notes that his work is exploratory and not designed to provide a new, all-encompassing theory, he claims that his approach to understanding the environment transcends the efforts of those writing (mainly in the 1970s) in the area of semiotics, human geography, and environmental psychology. After an assessment of the merits of the works of Bourdieu, Foucault, and LeFebvre, Shields leans heavily on them, borrowing their conceptual language. He stresses LeFebvre's notion of space, not as an external reality but as a concept that must be understood in terms of the meanings that people ascribe to it. Shields's central theoretical concept, "social spatialization," which refers to the connection between the social, the cultural, and the spatial, though defined in varied ways, is not particularly unusual.

The second part of the book, like the entire volume, is verbose, but unlike the introductory and concluding sections, it is genuinely interesting. It features four case studies in an effort to document that the images and stereotypes of places affect how people understand their worlds. Two places, Niagara Falls and the British seaside resort of Brighton, as well as two spaces (or regions), Northern Canada and the north-south divide in Great Britain, are discussed at length in an effort to illustrate the cultural significance of place images and meanings. Using diaries, films, television, print media, and academic accounts, Shields illuminates the role of the spatial in each of his place studies. While enlightening readers about how, say, Niagara Falls's place image was transformed from "a shrine to the power of Nature," to an "industrial powerhouse," to "honeymoon capital of the world," Shields fails to anchor his theoretical discussion adequately. Indeed, some key theoreticians, such as anthropologist Victor Turner, whose ideas Shields credits heavily in the Niagara Falls study, are not included in the theoretical introduction. More generally, although the studies adequately illustrate the sociospatial approach, they suffer from not being linked to a cultural theory that clearly shows the causal connections between the creation of place images and the actions of people.

The concluding section, a chapter entitled "Synthesis and Implications," falls short of convincing the reader that the text transcends contemporary sociospatial analyses. The strength of the book lies in Shields's use of case studies to demonstrate the import of the spatial in social practices. But the introduction and the concluding

section are somewhat confused, not well connected with the examples, and offer little to scholars familiar with the area. Minus the theoretical packaging, the case studies would warrant reading by novices and others less familiar with the socio-spatial perspective.

The Politics of Migration Policies: Settlement and Integration — The First World into the 1990s.
Edited by Daniel Kubat. Center for Migration Studies, 1993. 379 pp. $14.95.

Reviewer: OTIS L. GRAHAM JR., *University of California, Santa Barbara*

The first edition of this useful book appeared in 1979, exploring "surprisingly parallel" experiences of the nations of the First World (the industrialized countries of Europe, North America, and Oceania) with rising levels of emigration from the Third World in the 1960s and 1970s. That volume found that each of the 19 nations surveyed, from Austria to Australia, had been forced by incessant waves of south-north migration to "realize that in-migrations may have lost their justification." It concluded that concerns over emigration costs prevailed over traditional emigrant-welcoming attitudes and that the "in-migration overrun" of the countries of northwestern Europe was now checked by a turn to restrictive policies. As for the "countries supplying the migrants," they "have been forced to see that outmigration does not solve, but only postpones those problems which prompted it."

These words have an odd ring today, much as would any 1979 report from the Pentagon or CIA on the economic and political health of the menacing Soviet Union. Sending countries still send their millions of migrants, but at higher rates, and their governments apparently continue to postpone problems through out-migration rather than face them. This new, 1993 edition of *The Politics of Migration Policies* also reveals that most emigrant-receiving First World societies (Japan is an exception, and the picture in the vast territories of the former Soviet Union is formidably confused) continued through the 1980s and into the 1990s to absorb heavy waves of migration. The turning point forecast in the 1979 edition did not occur, apart from the termination of guest-worker programs; massive south-north migration accelerated, augmented by the dissolution of the Soviet Union. So much for prediction in the social sciences.

The essays in the new edition, many revised by their original authors, thus extend the story of south-north migration pressures to the threshold of the 1990s. The parallelism of emigration experience among First World nations has expanded beyond the inflow of rising numbers to include an almost universal increase in restrictionist sentiment. (The anthology misses the most intense period of emigration restriction politics that began in Western Europe and the U.S., especially California, in the early 1990s.)

It is useful to have an updated version of the original 1979 essays, along with new essays on Japan and the former Soviet Union. What do the 19 essays all add up to? They do not arrive at any particular conclusion, nor does the editor offer one. In his introduction to the new edition, Kubat ventures some cursory, optimistic thoughts. In view of the fact that the "population on this earth has passed the 5 million mark . . . the migratory flows in Europe seem manageable, which they are." For another flimsy insight, consider this: "A solution is always found and integration and settlement of the foreign population does take place." This bland superficiality

is followed by a sounder observation: "The chief question and concern remaining is to reconcile the political will of the government which errs on the side of benevolent enlightenment and the political will of the people who err on the side of dislike of foreigners' habits both at work and on the street and with whom they compete." Kubat is right that after three decades of emigration pressures on the First World, governments are out of touch with the anger of unconsulted citizens. As for the history-based consolation that "a solution is always found," Kubat's readers will want to consult Robert Kaplan's "The Coming Anarchy" in the February 1994 issue of the *Atlantic Monthly*. The future, Kaplan cogently argues, is going to be quite different from the past.

A volume coming out of the emigrant-advocacy Center for Migration Studies naturally votes for the benevolent acceptance of whatever international population movements seem under way. Although such is the thrust of this volume, readers are free to form their own conclusions from this conclusion-less but panoramic tour of one of the key dynamics of contemporary and future history.

Organizing, Role Enactment, and Disaster: A Structural Theory.
By Gary A. Kreps and Susan Lovegren Bosworth, with Jennifer A. Mooney, Stephen T. Russell, and Kristen A. Myers. University of Delaware Press, 1994. 221 pp. $38.50.

Reviewer: ROBERT A. STALLINGS, *University of Southern California*

Sociologists have been making important contributions to the understanding of disasters for at least a half century, but their research has had relatively little impact on sociology itself. Outside the field of collective behavior, little use has been made of their findings. This neglect is unfortunate, because disasters are natural laboratories wherein properties of social structures and processes are accessible to a degree seldom seen under more normal circumstances.

Gary Kreps, Susan Bosworth, and their research team have been at work for over a decade bringing data gathered in the aftermath of disasters to bear on such important questions about social organization as, What is the essence of organization? By what processes does it emerge, sustain itself, and change? Kreps and Bosworth's new book provides both a review of their earlier findings and a report on the most recent phase of their work, the latter of which involves building a formal theory of role enactment in disasters.

Kreps and Bosworth break down role enactment into three components. *Status-role nexus* refers to whether roles enacted by participants in organized disaster responses are consistent with their predisaster statuses. *Role linkages* identify whether postdisaster relationships reflect continuity with predisaster role sets (e.g., doctor and nurse) or discontinuity (e.g., a college professor and a meat inspector who form a search-and-rescue team). *Role performance* identifies various degrees of innovativeness both by incumbents enacting predetermined roles (role playing) and by those entering into disaster roles that are new to them (role making). Correlation and regression analyses suggest that stability (versus change) in role enactment varies directly with the severity of the disaster, the size of the community in which it occurs, the degree of continuity in the organizational structure, and the speed with which individuals become involved in the disaster response. Furthermore, stability varies inversely with the complexity of the division of labor in the organized response, the

extent to which postdisaster roles involve leadership, and the presence of previous community experience with disaster.

A methodological contribution of this project is its coding of a unique archive of qualitative data. Now housed at the University of Delaware's Disaster Research Center, the archive contains nearly 6,000 in-depth interviews gathered over 30 years on purposive samples of organizations and groups. These are unstructured interviews in which interviewees describe (as respondents) their own behavior during a disaster and (as key informants) characteristics of the organized responses in which they participated. Kreps and his team have coded over 1,000 interviews describing 423 organized responses. A nonrandom subsample of 257 individuals participating in these responses is used in most of the statistical analyses.

Those unfamiliar with Kreps's project will find this book difficult to read, not because of the writing (it is well written) but because the authors have been immersed in their work for so long that the reader will have to work hard to keep up with them. Those familiar with organization or role theories may flinch at some of the authors' conceptualizations and operationalizations. And the empirical work on role dynamics may ultimately uncover little that was not already suspected (e.g., role enactment is more stable within organizational forms that themselves display greater continuity).

Nevertheless, this is a book that sociologists in general — not just those already engaged in research on disasters — will find useful. Kreps, Bosworth, and their student collaborators document issues and steps involved in theory construction, present a formal theory of the dynamics of organizing and role enactment, and provide a detailed protocol to guide future efforts to test their theory with primary data. The book also contains a detailed accounting of successes and frustrations in converting existing qualitative materials into quantitative variables. Most important, the authors provide a primer on how the seemingly esoteric topic of disasters represents an excellent opportunity to explore fundamental questions of organization and organizing.

Participant Observer: An Autobiography.
By William Foote Whyte. ILR Press, 1994. 346 pp. Cloth, $52.00; paper, $24.95.

Reviewers: PATRICIA A. ADLER, *University of Colorado;* PETER ADLER, *University of Denver*

The author of our most enduring and widely read ethnography treats us to a first-person account of his life and times, an elegantly written and carefully documented portrait of the consummate scholar. Covering more than 50 years of his life in academia, Whyte takes his reader on a journey through three continents, four universities, and uncountable research sites. We learn about his family life, the influence of pivotal colleagues, and the effects of a near-debilitating battle with polio. All of this is played against the backdrop of the times in which he lived: before World War II he conducted the research for *Street Corner Society*; in wartime Oklahoma he made a brief, albeit important, foray into the oil industry; in the postwar period he found fertile ground for organizational studies in the manufacturing region surrounding Ithaca; in the tumultuous 1960s he served as a voice of reason in a Cornell racked by violent protest; and in the 1960s through the 1980s he honed his singular brand of applied sociology by integrating research, consultancy, and advocacy in community and organizational studies in Venezuela, Peru, and

Spain. Whyte's stories are told in brief vignettes, with each of the 42 chapters outlining a specific event or crucial epiphany in his life. While traversing this terrain, he offers a history of American sociology. The book is well written, with an eye for developing the relationship between personal biography and academic pursuits.

Though Whyte has not embraced some of the recent postmodern turns in the practice of ethnography, his autobiography can be read with a 1990s sensibility. We are reminded that, as revolutionary as the current practice of ethnography may feel, this important figure sowed the seeds for these changes long ago. As a "confessional" tale, the book poignantly and candidly recounts some of the foibles, drawbacks, and elation that ethnographers face during the course of a research project. Chapter 11, entitled "Learning to Be a Participant-Observer," is a veritable primer for the novice ethnographer on how to gain entrée to research settings. The book also reflects the current fascination with the role of self in qualitative research, exploring how the personal intermixes with the professional and how subjectivity operates to allow ethnographers greater access to their subjects. We also see aspects of the battle over voice and authority, where researchers have to grapple with how much they can speak for their subjects and how much they must allow indigenous populations to speak for themselves. Finally, Whyte's own contribution to ethnography — participatory action research — presaged the present-day focus on action and praxis in the conduct of research.

William Foote Whyte has provided another enduring document for future generations to read and ponder. Those who have already read his other personal accounts in the appendixes to the editions of *Street Corner Society* and his previous work *Learning from the Field* will find that their appetites have been only whetted for this thorough treatment. Though Whyte is best known for one book, his autobiography reminds us of how wide-ranging his contributions have been throughout his distinguished career (he has written or edited eight books since his retirement in 1979). This handsome volume, complete with priceless photographs, should sit proudly on any sociologist's shelf. It will serve as a motivation for productivity, creativity, and commitment to the academic enterprise.

Secularization, Rationalism and Sectarianism: Essays in Honour of Bryan R. Wilson. *Edited by Eileen Barker, James A. Beckford, and Karel Dobbelaere.* Clarendon Press, 1993. 322 pp. $55.00.

Reviewer: JOSÉ CASANOVA, *New School for Social Research*

This is a compilation of 16 essays written by eminent scholars in the social scientific study of religion. What distinguishes this well-deserved and rewarding Festschrift, giving it an unusual coherence for this kind of publication, is the fact that besides having been written by a group of colleagues who share "respect, admiration, and affection" for Bryan Wilson, the doyen of sociological studies of religion in Britain, the essays were specially commissioned for the book and revolve around the three concepts that have served as leitmotifs in Bryan Wilson's rich and influential lifework: secularization, rationalism, and sectarianism.

Some of the essays are only indirectly related to Wilson's work through thematic affinity. These include James A. Beckford's comparative discussion of the different patterns of governmental management of controversial new religious movements (cults) in the U.S. and the United Kingdom; Jean Séguy's historical reconstruction of

the apocalyptic theme in "Adventist" religious orders; Philip Rieff's literate and cryptic discourse, concatenated into 40 epigrammatic theses on the politics of culture and the culture of politics; and Asa Briggs's discussion of British religious broadcasting.

The essays by Karel Dobbelaere, Sabino Acquaviva, and Philips Hammond and Mark Sibley review the old paradigm of secularization in view of the numerous recent criticisms coming primarily from students of religion in America. From diverse perspectives, the essayists all support Wilson's defense of an unreconstructed paradigm that tends to treat the exceptional European case as a universal process of modernization. But this new round in the secularization debate only restates old platitudes. The main fallacy in the old paradigm, reproduced by apologists and critics alike, is the failure to distinguish analytically among three distinctly different, uneven, and unintegrated propositions: secularization as differentiation of the secular spheres from religious institutions and norms (which remains the valid core of the theory of secularization); secularization as decline of religious beliefs and practices (which remains an empirically valid proposition for some modern societies [e.g., Europe] but is patently invalid for others [e.g., the U.S.]); and secularization as marginalization of religion to a privatized sphere (which is a historical option for religions in the modern world). Only by examining and testing the validity of each of these propositions independently of each other can one hope to leave behind the fruitless secularization debate.

The rest of the essays take some of the central categories of Wilson's work and offer various reformulations of them, examine them critically in view of newer research, or apply them to new areas. David Martin, Michael Hill, and Susumu Shimazono investigate Wilsonian patterns of sectarianism respectively in Latin America, New Zealand, and Japan. Roy Wallis, Eileen Barker, and Richard Fenn examine uses of the concept of charisma and the dynamics of charismatization and domestication. The Africanist J.D.Y. Peel revisits *Magic and the Millennium* and returns convinced of the continuing relevance of the Wilsonian framework for the study of West African religion. Indeed, he asserts the analytical superiority of Wilson's typology of religious movements over the usually more contextualized but untheorized Africanist analyses. The most illuminating essays are by Roland Robertson and Richard Gombrich. Both offer a deconstruction of the essentialist category of "religion" as a modern Western construct. Robertson traces the genealogy of the category of religion, its discovery and uses by Western modernity, and its global diffusion and paradoxical indigenization in non-Western societies. Through a comparison of Sinhalese and Japanese Buddhisms, Gombrich traces the dissociation of secularization and Protestantization, two processes that appear intrinsically related in the Weberian-Wilsonian theory of rationalization. Overall, the Festschrift honors the complexity and widespread influence of Wilson's work and meets the expectations raised by bringing together such a roster of prominent scholars of religion.

Public Reactions to Nuclear Waste: Citizens' Views on Repository Siting.
Edited by Riley Dunlap, Michael E. Kraft, and Eugene A. Rosa. Duke University Press, 1993. 332 pp. Cloth, $49.95; paper, $24.95.

Reviewer: WILLIAM M. BABIUCH, *National Renewable Energy Laboratory*

Occasionally a book comes along that is "required reading" in a particular field. *Public Reactions to Nuclear Waste* is one such book. It contains a variety of essays that provide an in-depth examination of the social and political factors associated with the disposal of high-level nuclear waste. The empirical data will be valuable to both social scientists and policymakers as they seek a better understanding of the factors affecting public attitudes toward nuclear issues in hopes of efficiently and effectively resolving America's nuclear disposal problem.

The essays in this volume address broad-based issues related to nuclear waste, such as the context of public concern with nuclear waste and public reactions to initial attempts of the Department of Energy (DOE) to locate repository sites, as well as public opinion issues specific to the site at Yucca Mountain, Nevada. The authors use a broad range of data-collection techniques and provide valuable descriptions of their methodologies to allow the reader to understand the strengths and weaknesses of their findings.

While each essay addresses the issue from a slightly different angle, two key findings appear throughout the book. First, a high-level nuclear waste repository is unacceptable to most Americans for the foreseeable future because the associated risks are perceived to be too great. As noted in an essay by Desvousges, Kunreuther, Slovic, and Rosa, "Although [the respondents] show recognition of the economic benefits associated with the repository, [they] do not believe those outweigh the risks." Second, perceptions of the risks of a high-level nuclear waste repository are closely tied to trust in government and in agencies responsible for the repository management, especially DOE. This book strongly contends that restoring public trust in DOE's handling of nuclear matters is vital if America hopes to deal effectively with nuclear waste. The importance of trust has not gone unnoticed by DOE. In April 1991 Secretary of Energy Watkins created the Task Force on Radioactive Waste Management to recommend measures that DOE might take to strengthen public trust and confidence in the civilian nuclear waste management program. The report issued by the task force states: "It is the strong view of the Task Force that DOE stands little chance of strengthening public trust and confidence unless it recognizes that its decision-making behavior will have to fundamentally change." The report goes on to call for greater inclusion and empowerment of parties external to DOE in the decision-making process. Although DOE is making an effort to restore public trust and confidence, findings presented here confirm that it will be a difficult task, for "it is much easier to lose people's trust than regain it."

In combination with sound empirical analysis of the public's attitude toward nuclear waste, this book examines policy prospects for the future of nuclear waste. In the closing essay, Rosa, Dunlap, and Kraft assess the value of "traditional fixes" and express concern that each of these fixes minimizes direct public participation. Such minimization runs counter to recommendations made in the DOE task force report as well as in this volume. Kraft and Clary contend, for example, that even though public hearings are one way to obtain public input, more meaningful public involvement is necessary if DOE hopes to restore its credibility and find a publicly acceptable solution to the problem of nuclear waste.

In my work as an energy analyst I have heard DOE policymakers stress that they "need substantive data to support claims about the public's perception of energy-related issues." This volume meets that need, providing data on the public's opinion of nuclear energy in general and nuclear waste in particular. The book will be an invaluable contribution to the resolution of America's nuclear waste disposal and should be read by all social scientists and policymakers involved in this issue.

Continual Permutations of Action.
By Anselm Strauss. Aldine de Gruyter, 1993. 280 pp. Cloth, $44.95; paper, $21.95.

Reviewer: GARY ALAN FINE, *University of Georgia*

Perhaps no sociologist of the past half century — with the possible exceptions of Erving Goffman and Robert Merton — has been as generous in creating a string of provocative middle-range concepts, given freely to the sociological community, as has Anselm Strauss. In his latest contribution, forgettably entitled *Continual Permutations of Action*, he sets out to develop a "theory of action" — that holiest, elusive grail of sociological endeavor, the Unified Field Theory. If the field is not so easily unified and action not so easily known, it is not for want of worthy attempts.

In fairness, the book should not be considered a grandly synthetic work but rather an important summation of the relations among the constructs that Strauss has developed over his long career. It is a return to certain basic concerns that he addressed in his important 1959 volume, *Mirrors and Masks*, and that have animated his career. (It is astounding to recognize that *Mirrors and Masks* was a midcareer contribution, and if his productivity proceeds apace, *Continual Permutations of Action* will be as well.) In *Mirrors and Masks*, Strauss argues, probably more effectively, if with less bravado, than does Goffman in *Presentation of Self*, that actors are lodged within a nexus of interaction and structure.

Action consists of the possibilities of linkage between the individual and a variety of social structures as mediated through situations. Strauss's theoretical perspective, which emphasizes the centrality of collective action, is in direct line with the pragmatism of Dewey and Mead: the focus is on the ongoing components of *acting*. Strauss underlines the contingent nature of social order in collective action, a processual view that has posed barriers to the creation of an interactionist version of social organization. How can organization be powerful in a world of contingencies? Strauss's particular contribution is to outline the bridge between an actor's choices and the reality of structure.

Most of Strauss's numerous concepts — among them, the arc of work, negotiated order, awareness contexts, and policy arenas — share a creative tension between acting and constraint. The reality of the other provides an arena in which meaning is created and interaction generated. This model is distinct from unmoored visions that assume the nearly unbridled creative power of the mind. Strauss gives primacy to neither cognition (strong social constructionism) nor affect (certain strains of postmodernism). In contrast, the primacy of acting reminds us that this grand theory is a branch of social behaviorism — behavior that is limited, contextualized, constrained.

Unlike Strauss's rich treatment of action, context, and organization, his theory of self is markedly attenuated. If, as has been said, interactionists come in two flavors, self-theorists and situation-theorists, Strauss is of the latter breed. The body

has more weight than the soul. Whereas Blumer keeps searching for the self — the core, I — Strauss hardly notices its absence as long as a body is present to act and a biography remains as an evidentiary record to be employed in the creation of relations.

Strauss begins *Continual Permutations of Actions* by modestly acknowledging that he did not consider himself to be a social theorist until colleagues urged him to make his model less implicit. As one colleague is quoted as saying, "Some of your best ideas are in your subordinate clauses." The reader may find this oddly insightful comment simultaneously valedictory and critical. One completes the book without having confronted a grand theory but having had numerous — perhaps too many — encounters with ideas and images. (For evidence of this cornucopia, compare Blumer's *three* premises of symbolic interaction with Strauss's *19* assumptions.) This volume, which explicitly attempts to generate a theory of action, can most properly be said to provide the tools by which an integrated model *might* develop. Too much is provided to be considered parsimonious, but just enough to allow us to glimpse a set of complex truths.

In the end this book proves not to be the simplified, explicit "theory" that Strauss's colleagues had wished, but it represents Anselm Strauss at his theoretical prime: the master of the sensitizing concept.

Editors as Gatekeepers: Getting Published in the Social Sciences.
Edited by Rita J. Simon and James J. Fyfe. Rowman & Littlefield, 1994. 275 pp. Cloth, $53.50; paper, $22.95.

Reviewer: MICHAEL SCHWALBE, *North Carolina State University*

Suppose we wanted to know how corporate elites keep their boardrooms looking so white and male. One way to find out would be to ask them. A likely response might be, "We don't discriminate. We look for qualified people who are team players, people we feel comfortable with and can trust to do what's best for the company. Gender and race have nothing to do with it." After collecting many such accounts from articulate, polite, and sincere executives, it might begin to seem that charges of racial and gender bias are nothing but ego balm for sore losers.

Suppose we wanted to know how editors make decisions. One way to find out would be to ask them. If we put their answers into a book, the result would look like Simon and Fyfe's *Editors as Gatekeepers.* In this book, editors of journals in various disciplines and editors of commercial and university presses give accounts of what they do, how, and why. But like the accounts we might get from corporate elites about how they reproduce themselves, these are more valuable as data than analysis.

This is not to say that the accounts in this book are uninteresting or ring false. In fact, the authors seem to be trying hard to offer an honest look backstage. There are even some surprisingly frank confessions.

For example, former *American Sociological Review* gatekeeper Rita Simon says, in her contribution to the volume, that an editor who dislikes a paper that has nonetheless received two positive reviews can send it out again, into the jaws of tougher critics, who are likely to provide justification for the decision toward which the editor is inclined. To us commonfolk this might seem unfair, but as Simon

explains, editors are people of extraordinary talent and accomplishment, and thus deserve the freedom to maneuver in these ways.

In other chapters we learn that some journal editors prefer to publish papers that give their disciplines the appearance of coherence; that a paper for which an editor cannot quickly think of a reviewer is probably doomed; that for some editors the first step in the review process is to identify the author as a bigshot, master craftsman, junior apprentice, or crank; that the review process treats everyone alike; that apostates of positivism are unlikely to be chosen as editors; and that most complaints of bias on the part of rejected authors are unfounded since, as these editors attest, the system works pretty darn well.

These tidbits suggest some of the contradictions within and between the book's chapters. There are others. For example, peer review, we are told, encourages writers to perfect their papers before sending them out; yet this flies in the face of the 90 percent rejection rates at top journals. We are also told that editors use rigorous, universalistic standards for evaluating papers; yet this contradicts other confessions about how the process is manipulated to get the results editors want. And then we are told, over and again, that the review process is healthy, even though 41 percent of sociologists say that the articles in major journals are boring and even though about 70 percent of those articles are never cited.

It would have been nice if Simon and Fyfe had taken these contradictions as starting points for a more critical analysis of how editors tend their gates and what the results are. It would also have been nice to see the chapter authors, or Simon and Fyfe, interrogate their ideas about what constitutes an important, useful, original, and insightful contribution — as many speak of looking for. What is considered important and useful? Why?

When corporate elites tend their gates, they give similarly vague accounts of the criteria they use to decide who gets in. Those accounts may be revealing in some ways, but they are not *explanations* of what really goes on. We should not expect otherwise. Gatekeepers are, by definition, committed to reproducing, not critically analyzing, the communities that put them at the gates. To understand more deeply what they do and why, it is necessary to examine what gatekeepers take for granted, much of which remains taken for granted in this book.

Publishing junkies, gripers, cynics, and curious graduate students will probably enjoy *Editors as Gatekeepers*. Some of the essays are a bit clunky and annoyingly self-congratulatory (the gate should have been narrowed, let's say), but on the whole they are easy to read. I doubt that the book will really save neophytes much "time and pain," as Simon and Fyfe claim. But at least it will give them a better idea of the grief they're in for.

George Herbert Mead: The Making of a Social Pragmatist.
By Gary A. Cook. University of Illinois Press, 1993. 240 pp. Cloth, $31.95; paper, $15.95.

Reviewer: HOWARD L. SACKS, *Kenyon College*

Over the last decade, the work of George Herbert Mead has been a subject of renewed interest and critical examination. Scholars have linked Mead's thought to European sociological and philosophical traditions and have expanded the available body of Mead's work through the publication of previously unpublished essays and

his students' lecture notes. Taken together, this scholarship has reestablished Mead as a seminal American thinker whose ideas have contemporary significance for sociology. In part, recent scholars have accomplished this task by wresting the Meadian legacy from the grasp of symbolic interactionism, which has too often distilled and trivialized Mead through a narrow reading of only a portion of his writings.

Gary Cook's intellectual biography contributes to this expanded view with a careful textual examination of Mead's book reviews, scholarly essays, and writings associated with his social reform activities in Chicago throughout the first decades of this century. Cook begins, appropriately, with Mead's early development at Oberlin College and his philosophical studies at Harvard and in Germany. Here we learn of the intellectual dilemmas that engaged Mead and his close friend Henry Castle and that would animate Mead's later scholarly and reform activity. From the beginning, Mead sought a rational understanding of human experience that overcame the a priori constraints he saw in both Kantian metaphysics and Christian spirituality. Writing to his friend, Mead disclosed the fear that he had "too much reason and too little strength to be a Christian, and too little reason and too much sentiment to be a philosopher."

Mead found the solution to this dilemma in a dynamic social psychology that remains his most original intellectual contribution. Working closely with his colleague John Dewey, Mead strove to overcome the mentalism and dualism of existing approaches to identity in favor of a functional psychology that emphasized social conduct as the wellspring for defining individual identity and social reality. By grounding identity in social conduct, Cook notes, Mead discovered an alternative to the "assumption that one must opt either for the older conception of consciousness as involving special mental substance or for an outright denial of the existence of consciousness." But although Cook examines the development of Mead's formulation of the social self in great detail, he fails to articulate fully Mead's ideas on the dialectical character of social conduct. Instead, Cook vaguely attributes Mead's dialectical thought to the influence of Hegel, obscuring Mead's more materialistic approach. This is an unfortunate omission, for several reasons. First, the dialectical character of Mead's theory of self, embodied in the concepts of the "I" and the "me," has been a source of considerable debate and confusion. Cook's otherwise painstaking examination of Mead's key ideas might have done much to clarify these central but elusive concepts. Second, by largely ignoring these concepts, Cook repeats the weakness all too common in symbolic interactionism's treatment of Mead, which has contributed to a misunderstanding of Mead's social psychology as consistent with sociological functionalism. Finally, this omission limits our ability to understand the crucial link between Mead's social psychology and his social activism.

Cook makes his most original contribution in his examination of Mead's reform activity and pragmatic vision of social reconstruction. Through their involvement in educational and labor reform and in the settlement of immigrants, Mead and Dewey constantly tested their ideas about society, an empirical moment sociologists have generally overlooked. Cook clearly reveals Mead's valuing of the scientific method as a vehicle for intelligent social change. Nevertheless, Mead rejected a positivist approach that would disallow the scientist's participation in morally grounded efforts at social reconstruction. As Cook so ably demonstrates, in Mead's work, social theory, scientific method, morality, and social praxis are phases of a single

process of constructive action. Taken together, these strands constitute Mead's pragmatist vision.

The serious student of Mead will find few new insights here, but the sociologist with a more casual understanding of Mead's work will gain a deeper sense of Mead's key ideas from this ably argued and straightforward presentation. In Cook's portrait of George Herbert Mead we find a morally engaged teacher and scholar whose intellectual life is inextricably bound to the betterment of his community. It is a model that sociologists, too often removed from the world they seek to understand, would do well to emulate.

Simulating Societies: The Computer Simulation of Social Phenomena.
Edited by Nigel Gilbert and Jim Doran. UCL Press, 1994. 306 pp. Cloth, $59.95.

Reviewer: KENNETH A. BOLLEN, *University of North Carolina at Chapel Hill*

Simulating Societies grows out of an international symposium of the same name that was held in 1992 at the University of Surrey, Guildford, England. The book has 12 papers by 23 contributors. Doran and Gilbert's introductory chapter provides a definition and overview of simulation models. They use the collapse of Mayan society to illustrate some of the ideas. Despite the concrete example, the presentation tends to the abstract. Séror's chapter provides an overview of different simulation strategies and their epistemological dimensions. Troitzsch's chapter is more concrete. He examines the evolution of hunting and gathering, agrarian and industrial technologies in fragmented populations. Nowak and Latané describe a simulation program that explains how the attitudes in a population can change due to the strength and immediacy of the attitudes and the number of people holding different or similar attitudes. The chapter by Penn and Dalton discusses urban traffic but has implications for the broader understanding of spatial factors on human behavior. The details and data of this chapter exceed those of the earlier ones. An ant colony simulation is the subject of Drogoul and Ferber's chapter. Of most relevance to sociologists is their discussion of a method where macro behavior is built from micro behavior.

A chapter by Bousquet et al. considers the interaction between people and environmental resources in a society of fishermen while Mithen's chapter simulates prehistoric hunter-gatherer societies. Mithen's review of the major simulation approaches to hunting and gathering societies is quite informative. The chapter by Doran, Palmer, Gilbert, and Mellars is a progress report on a large simulation for modeling upper Palaeolithic social change. Reynolds uses what he terms *cultural algorithms* to study the microlevel evolution of individual traits and macro-evolutionary changes in beliefs. They use this approach to simulate the rise of cooperation among llama herders on the punas of Ayacucho, Peru.

José Castro Caldas and Helder Coelho have one of the most interesting chapters in the volume. They examine bounded rationality and oligopoly among economic agents in markets. I particularly liked their use of human experiments that they analyzed prior to replacing the human agents with simulation ones. Such an approach gives greater validity and realism than is typical in simulation models. Conte and Castelfranchi's concluding chapter is a critique of artificial intelligence models of social action. More specifically, they question the assumptions of agents' cooperation, full information, and rationality.

The collection of chapters may be viewed as a social scientific sampler of simulation models. Much of the work comes from anthropology, social psychology, and economics. Though Doran, a coeditor, is a sociologist, the influences of these other social sciences far exceed those of sociology. This is more a reflection of the relative neglect of simulation research in sociology than a failing of the book. Indeed reading this collection of papers made me wonder why simulation techniques are not more widespread in sociology. Undoubtedly, the oversimplistic simulation models from the 1960s and 1970s left many sociologists skeptical of such an enterprise. Also, the small percentage of sociologists trained in the mathematical and computer programming skills that are required for such efforts limits the pool of researchers capable of conducting such simulations. Nevertheless, several papers in the volume examine issues of intense current interests in our discipline — e.g., the construction of macro structures from the behavior of individuals, the intersection of sociology and economics, the linkages of society and environment. Perhaps it is time for sociologists to take another look at simulations. This edited volume is a reasonable starting point to sample projects from neighboring disciplines.

African Americans: Essential Perspectives.
Edited by Wornie Reed. Auburn House, 1993. 160 pp. Cloth, $49.95; paper, $16.95.

Reviewer: MARLESE DURR, *Wright State University*

The four original essays in this book suggest that social, economic, political, and judicial issues in the African American life cycle require compacted analysis. An underlying theme is that small societal changes since the 1960s have recast African Americans' social status, but structural and economic changes may have slowed their further progress. A second cleverly veiled theme presents African American value orientations as by-products of our racial stratification system. The first two essays relate specific historical parallels to what the authors consider to be the current condition of African Americans — perseverance despite small-scale social change.

The third essay addresses structural changes within the economy, giving special emphasis to labor market reconstruction, which the authors contend is now managerially based. The critique implies that the transition in authority structure from capitalists to managers and policymakers marginalizes African American managers and policymakers, who mostly supervise the African American working class. This raises the questions of ways that African Americans can act independently of the "public sector" helping positions that have historically been their role as public servants, and how they can gain admission to newer occupations.

Acknowledging that African American political participation was and is a search for power, the authors advise persistent use of traditional and nontraditional methods of dissent to realize the goal of social and political parity. The highlight for readers here is the speculation about the growing number of African American conservatives. The authors explicitly claim the presence of a strong liberal orientation among African American conservatives, while subtly positing that this information might have been known to social science researchers had they made a systematic study of political attitudes for this social group.

The final essay underscores race as a significant factor in the examination of issues of justice. Discussing sentencing, capital punishment, juvenile justice, and

drugs, the authors suggest four issues that need scholarly investigation: (1) discrimination in the plea bargaining process; (2) different treatment of African American female and male defendants; (3) the importance of the race of the victim; and (4) discrimination in the formal parts of the criminal justice process. In addition, these authors note the paucity of investigation regarding the decision to reject bail and the dismissal of charges once filed. Citing ambiguous and contradictory data on minority youth crime, the authors briefly discuss the discretionary power of the juvenile justice system and its severe impact on employment opportunities for African American youth upon release.

These essays may not provide new data, but their historical comparisons offer food for thought and suggestions for further research.

The Classic Roots of Ethnomethodology: Durkheim, Weber, and Garfinkel.
By Richard A. Hilbert. University of North Carolina Press, 1992. 260 pp. $39.95.

Reviewer: JAMES J. DOWD, *University of Georgia*

It is interesting to consider the corrosive and redefining properties of time and history. The challenge to mainstream sociology posed by the ethnomethodological "movement," as some (see Pierce J. Flynn's *The Ethnomethodological Movement* 1991) consider the writing and research of Garfinkel, Cicourel, Sacks and others to be, no longer seems quite so interesting. In fact, in the wake of the postmodernist surge, this challenge seems remarkably conservative in its insistence on the precise analysis of carefully coded conversations and other discourse. Hilbert's analysis of the elective affinities between ethnomethodology and the writings of Durkheim and Weber has much to recommend it but also suffers from a lack of originality that, given the author's focus on the arcane niceties of whether Parsons or Garfinkle provides a better reading of Durkheim and Weber, consigns this book to the farther reaches of the shelf.

The central themes of Hilbert's argument have already been developed in John Heritage's *Garfinkle and Ethnomethodology* (1984), which Hilbert cites with admiration. Hilbert's thesis is that Parsons, while justifiably important for his integration of classical writers like Weber and Durkheim, also suppressed some of their essential insights and directly negated some of their other lines of argument. Parsons's student, Garfinkle, in his empirical ethnomethodological studies, reclaims these suppressed and negated themes in Durkheim and Weber. In this sense, ethnomethodology is true to the classics. Ethnomethodology is much closer to Durkheim's original analysis of anomie, for example, than is Parsons, who claimed that anomie leads to behavior breakdown. Ethnomethodology is also much closer to the Weberian emphasis on the empirical study of ideas in history than is Parsons's preference for conceptual work. For Weber, the normative order has no place at all in sociology while, for Parsons, it exists as a second, separate order apart from a factual order. While Hilbert is on solid ground in his critique of Parsons's claim that a normative order exists separately from and prior to the factual order of behavior, the deconstruction of the Parsonsian claim that values drive behavior is not original with Hilbert but has been accomplished by others, most notably by Swidler in her oft-cited paper, "Culture in Action" (1986).

Apart from offering an apologia for ethnomethodology, Hilbert also claims to show that functionalism should be understood as a good instance of Weberian

rational-legal bureaucratization. His intent, then, is not only to provide a strong rationale for ethnomethodology's support of sociology's most productive traditions, but also to demonstrate, as if such demonstration were necessary, that the functionalism of Parsons is flawed. Ironically, however, one is left more sympathetic to Parsons after reading Hilbert than one may have been before. It makes little sense, after all, to insist that because one may gain a new appreciation of Weber or Durkheim after a close reading of Garfinkle, earlier readings of the classics such as, in the present case, Parsons's own classical interpretation from *The Structure of Social Action* must therefore be false.

Neither is Hilbert persuasive in his argument that it has been Durkheim, Weber, and Parsons, rather than the phenomenologists Schutz and Husserl, who have served as the major influences on Garfinkel. The influence of Schutz and Husserl, as well as Parsons, on the sociological imagination of Garfinkle cannot be gainsaid. Not only did Garfinkle attend lectures by Schutz, cite his work continually, and incorporate phenomenological ideas and assumptions into his own work, but his teacher (Parsons) himself is known to have carried on a lengthy correspondence with Schutz.

Toward the end of this book, Hilbert completes his case on behalf of ethnomethodology's importance to sociology by arguing for its compatibility on key issues with other sociological theories such as neofunctionalism, Collins's conflict theory, Giddens's structuration theory, and even Marxism (not to mention Durkheimian and Weberian approaches that had been examined previously). In summary, then, Hilbert offers a provocative and informative discussion of ethnomethodology's roots in the classics, via its encounter with Parsons. Since Garfinkle's project is a radically empirical one, it has never fully developed its theoretical implications or retraced its own theoretical lineage. It is this latter task that Hilbert has successfully accomplished in this work.

Frames of Remembrance: The Dynamics of Collective Memory
By Iwona Irwin-Zarecka. Transaction Publishers, 1994. xiv + 214 pp. $32.95.

Reviewer: JEFFREY K. OLICK, *Columbia University*

On the evidence of this book, Iwona Irwin-Zarecka is a dedicated and good teacher. *Frames of Remembrance* lays out in an accessible, interesting, and thorough manner major methodological and substantive issues in social memory studies. She demonstrates to the novice sociologist as well as to those new to the specialty why we should care about memory. She discusses the multiple forms it may take and roles it may play and gives good advice about how to study it. The book is impressive in the scope of issues it raises and examples it provides, and it is filled with good common sense for those headed into the field.

The book is divided into three major sections. In the first, Irwin-Zarecka justifies a sociological approach to memory and provides a basic orientation drawn on Goffman's frame theory. In the second section, called "Dynamics of Relevance," she reviews various modes, locations, and processes of collective remembrance, including its contribution to identity, its essentially contested nature, its embeddedness in material and popular culture and contemporary politics, as well as its connections with images of the future. The third section focuses more on the social action involved in memory production, including the social organization of

forgetting, memory projects, and the role of opinion leaders in transmitting particular images, interpretations, and constructions of the past.

Throughout the book, the author emphasizes that collective memory is an ongoing process and project. This is a salutary corrective to prevalent presentist approaches in the field — those which see the past either as a tool in social struggles or as their thoroughly malleable outcome. In addition, the author's moral and political concerns are of the sort that are inspiring to students and remind us all of the value of our enterprise. Irwin-Zarecka does not hide her potent worries about the fate of memory, particularly of Holocaust memory, and the Polish case she wrote about in an earlier book forms a backdrop for the entire enterprise.

As a chatty introduction and illustration for undergraduates, and as good advice to graduate students, the book is a worthy contribution. But it is just these strengths, as well as other problems, that prevent the book from making a major contribution to the field. First, the overly conversational tone and digressive writing works in favor of accessibility and relevance but against systematic presentation. This is not wholly unintentional: the author describes the book as "'a meeting place' allowing for an exchange of ideas, concerns, and findings"; the chapters are conceived as "relatively self-contained units, as diverse 'entry points' defined by questions rather than the lines separating disciplines or empirical territories." This strategy, however, seems more suited to asking questions than to answering them. As a result, the presentation is redundant, and divisions seem rather arbitrary. The style and form seem better suited to the classroom than the printed page.

Second, however, these matters have a more substantively troubling programmatic source. The author advocates what she calls a "context-sensitive approach," one that seems to abjure most theoretical and generalizing discourse. She argues that "it may be a long time before there is an analytical agreement on the dynamics of collective memory" and suggests that "as students of the dynamics of collective memory, we may be best advised to stay with the smaller [questions]. . . . The very complexity of the patterns we have found . . . point out the need for scaling down the inquiry." On this point, I strongly disagree. If ever there were a field overrun by unconnected case studies and in desperate need of theory and synthesis, it is social studies of memory. The author provides a useful annotated bibliography at the end, but the book does not come close to being representative, and it does not include some of the most prominent theoretical treatises in the field. Irwin-Zarecka recognizes the dispersion of the enterprise across disciplinary and geographical boundaries and adduces many examples to illustrate problems, but she seems explicitly to avoid synthesis and summary. Indeed, the book lacks a conclusion both formally and substantively.

In sum, *Frames of Remembrance* provides a useful introduction to issues and a good methodological guide, but avoids more definitive gestures, for which I think the field is ready. Nonetheless, if the book is more propadeutic than profound, it is still very much worth a look.

Class Structure and Social Transformation.
By Berch Berberoglu. Praeger, 1994. 122 pp. $45.00.

Reviewer: RANDY HODSON, *Indiana University at Bloomington*

Those interested in an orthodox Marxist interpretation of class structure for their undergraduate courses on social stratification will want to consider this book. It thoroughly develops the idea that class inequality is the central defining characteristic of modern societies.

The first chapter presents a range of theories of social stratification (mainly functionalist, Weberian, and elite theories) and criticizes these from a Marxist standpoint. Marxist class theory is presented next in a straightforward manner by a review of well known material on historical materialism, class as such and class for itself, ideological hegemony, and the role of the state in enforcing class inequality.

Subsequent chapters present a history of class societies and discussions of the current class structures of advanced and Third World societies. The chapter on the history of class societies is perhaps the least strong of these. Too much credit is given to Marx and Engels as historians, and much of the history of class inequality is seen through the lens of their very early understanding of these topics, including their writings on Oriental despotism. The chapter on classes in advanced societies is interesting and readable. The chapter on the Third World is perhaps too detailed. Too many continents, subregions, states, and time periods are reviewed in too brief a period to be easily digested by novice readers.

In the final set of chapters, Berberoglu argues that the understanding of racial inequality, nationalist movements, and gender issues must be based on an analysis of their class content. Berberoglu convincingly argues that national struggles are often motivated by class exploitation between nations. He presents analogous arguments for the class content of race and gender conflicts.

The merits of this book include its brevity, its general accessibility, and its doctrinaire approach. These strengths will make teaching Marxist class analysis from this book relatively straightforward. The content is organized with pedagogy in mind. Students who complain about long readings will appreciate chapters that are on average 12 pages in length (excluding notes). Its merits, however, also constitute limitations. No time or energy is spent considering the limitations of Marx's ideas and concepts that have been revealed by the century and a quarter since his major writings. The decision to present the material in this way may work as a pedagogical device, but an unconsidered presentation of Marxist class analysis is not very intellectually satisfying in today's world and some instructors may have reservations about presenting such ideas uncritically to their classes.

Programmatic statements and questionably grounded visions of nascent proletariat revolutionary movements in both the industrialized and developing worlds may tilt the balance against this book for some instructors. For example, in a section on class struggle in the U.S., the author predicts that: "The limited but real victories achieved in rank-and-file struggles of the past two decades are a beginning for longer-lasting, protracted struggles . . . so that the 1990s (as were the 1930s) would once again become a decade of militant labor struggles at the grassroots level." Similarly, in a discussion of class struggle in the Third World: "The material conditions that have led to U.S. imperialist domination of the world economy up to the present period have now reached a point where broad segments of the masses in the Third World are coming together to challenge it at its very foundations."

On the other hand, for those who like their Marxism straight, such programmatic statements and projected scenarios may be part of the content they want and expect. If this is the case, then this may well be their book; it is loyal to Marx's theoretical tenets and is pedagogically oriented and generally well written.

Parents, Their Children, and Schools.
Edited by Barbara Schneider and James S. Coleman. Westview Press, 1993. 192 pp.

Reviewer: SOPHIA CATSAMBIS, *Queens College, City University New York*

This is the first major publication on the effects of parental involvement in children's education that is based on large-scale survey data. It consists of a series of carefully conducted research papers that use the National Education Longitudinal Study of 1988 (NELS88), a survey of 26,000 eighth graders, parents, teachers, and school administrators. Specifically, it explores how families of different social and economic conditions attempt to further their children's education. It provides empirical evidence supporting the belief that parental involvement improves children's learning opportunities and school performances.

This investigation covers different types of involvements: parental home-based involvement of discussions with children about their educational experiences and plans, supervision of after-school activities, and savings for college; parental community involvement, like contacts with other parents; and parental school involvement, like volunteering at school and participating in parent-teacher organizations.

Some of the study's most significant findings concern race and ethnic variations in patterns of parental involvement. White parents tend to view education as cultural enrichment. They engage in activities that are social in nature, like discussing school with children, knowing their children's friends, and volunteering at school. African-Americans frequently speak with their children about school and are active in parent-teacher organizations. They are the group most engaged in "crisis intervention" activities that involve academic matters, like checking homework and contacting schools. Asian American families expend most of their efforts and resources on out-of-school educational activities. Finally, Latino families have the highest current school expenses.

African American and Latino parents, in comparison to whites and Asian Americans of similar social background characteristics, have the most significant school involvement. The schools that many minorities attend promote high involvement levels by employing minority teachers and by initiating frequent parent contacts. However, although many minority parents seek to compensate for economic or social disadvantages through active parental involvement, they cannot eliminate all of the educational disadvantages that their children face.

Additional findings show that students from all family types benefit from high levels of parental involvement and that various types of involvement affect students' performances differently. Home-based parental involvement mostly affects students' test scores, while school and community-based involvement mostly affects their grades.

Variations in levels of parental involvement partly explain socioeconomic and family-type differences in students' achievements. For instance, parental involvement partly explains the higher performance levels of students from traditional two-parent

families over students from five other family types. Moreover, families in which mothers work part-time have the highest frequencies of all forms of parental involvement.

This study also considers school choice, within the public or private sector, as an indicator of parental involvement. A series of complex analyses reveals that, unlike minority parents, white parents with low levels of education are generally not responsive to opportunities for school choice.

Overall, this book enhances the limited knowledge about parental involvement and identifies important issues. For example, many current policies seek to improve minority achievement by encouraging parental involvement, yet these policies may be based on erroneous assumptions because minority parents are quite active. Therefore, how can parental involvement translate into higher student achievement in schools that serve minority populations?

More research is needed concerning successful parental involvement and how it can be translated into higher achievement levels, increased school engagement, and greater success in all levels of education. NELS88, with its subsequent follow-up surveys of students and parents, will continue to be an essential data source, and the researchers in this series of papers are highly likely to produce future insightful analyses.

Professional Women at Work: Interactions, Tacit Understandings, and the Non-Trivial Nature of Trivia in Bureaucratic Settings.
By Jerry Jacobs. Bergin & Garvey, 1994. 144 pp.

Reviewer: DEBRA RENEE KAUFMAN, *Northeastern University*

The author of this highly readable and compact book touts its importance as one of the few attempts to study work from a qualitative perspective. Jacobs offers *Professional Women at Work* as one way to increase the number of studies offering "rich descriptions of work and the work experience." While I applaud the motivation to move from a positivist emphasis in the study of work to a qualitative one, it is not so clear that ultimately the author delivers the "rich data" the reader expects. Nor do I agree with the strong implication that qualitative studies often fall into the category of the "nontrivial study of trivia." To describe the routine, everyday experiences of respondents on the job as trivia unintentionally supports the notion that there are more profound issues in the sociological study of work. If the study of "trivia" leads to an understanding of how workers come to know and to do their work, then why continue to call it trivia?

I much prefer Jacob's reference to his case studies as "biographies of work" based on interviews with five women: a publications coordinator, an administrative analyst, a child-care administrator, an HIV clinic administrator, and a clinical psychologist. Although Jacobs argues that these are not gender related biographies, closer inspection reveals that, for the most part, the women under study are in the "female sector" of the professional labor force. That is, they are either in middle-management positions within public institutions or in stereotypical nurturing or helping occupations. Gender and race are not randomly distributed in the professional hierarchy. A host of data suggest that ascriptive characteristics do make a difference in how you and your work are perceived, evaluated, and consequently acted upon. By not exploring the gendered context of their experiences in the labor

force, Jacobs misses an important component of the ways in which women negotiate their day-to-day realities. This is particularly true when he discusses their complaints of powerlessness and attributes it primarily to bureaucracy.

Without a detailed description of the context for women's labor market activity, the data lack what Gertz would call "thick description." Except for scattered references about demographics, there are very few examples of how the personal and public lives of these women converge. Similarly, more illustrations would help to buttress the point that the meaning of work is constructed through the innumerable interactions and negotiations that occur on a day-to-day basis. Nonetheless, the book represents a healthy direction for research on women and work in the contemporary U.S.

Circles and Settings: Role Changes of American Women.
By Helena Znaniecka Lopata. SUNY Press, 1994. 325 pp. Cloth $54.50; paper, $17.95.

Reviewer: JENNIFER L. PIERCE, *University of Minnesota*

Helena Zopata's most recent book is a comprehensive overview of the changing roles of American women over the past century. Drawing from her own research, which spans almost 30 years, as well as the extensive literature in the sociology of gender, Lopata employs a feminist symbolic interactionist perspective to examine women's varied roles over historical time and across the life cycle. Her main interest lies in exploring the role clusters women assume (e.g., mother, wife, and paid worker), the resources they have with which to perform these roles, and the level of social and psychological commitment they have to these various roles.

Central to Lopata's analysis is the distinction between traditional, transitional, and modern roles for American women. Traditional roles are enacted in the context of agricultural and pre-industrial societies. She explores these roles in the history of the U.S. as well as other countries. Modern women, on the other hand, are flexible, "highly individuated and competent to function in a complex, industrialized society." While some American women adopt modern roles, Lopata finds that most women today perform their roles in an intermediate or transitional fashion. (In transitional families women assume primary responsibility for raising children.) She examines the diversity of women's experiences not only in terms of these ideal types, but also within the context of social class, and racial and ethnic differences.

The book is divided into eight chapters. Chapter 1 reviews role theory from a symbolic interactionist framework with *role* as a negotiated set of relations. For students unfamiliar with this theoretical approach, this chapter provides a useful overview to key concepts used throughout the book. The next four chapters focus on women's familial roles as wives, mothers, kin members (daughters, sisters, and grandmothers), and homemakers. The fifth and sixth chapters explore a variety of roles outside home and family, including employer, employee, student, friend, neighbor, volunteer, and activist. The final chapter focuses on conflicts and strains that women face today.

One limitation of the book is Lopata's conceptual emphasis on women's familial and domestic roles. By devoting so much attention to these role clusters, Lopata appears to uncritically accept the notion that women's roles are defined by their relationships to their husbands or to their children. As a consequence, the book contains little or no discussion of heterosexual single women, lesbians, or women

who marry but decide not to have children. Despite this limitation, Lopata does an excellent job highlighting the conflicts experienced by a diverse group of married women with children through their involvement in modern and transitional roles. When both spouses work in highly demanding jobs, most wives and husbands fail to meet a modern arrangement with equal treatment of the demands of two jobs. Women still find themselves making adjustments to their husbands' careers and doing more child care and housework than their spouses do. According to Lopata, part of the problem is the lack of institutionalized support for women's modern roles. Though the burden of child care and housework still falls on women who work in the paid labor force, most workplaces are unwilling to accommodate women's familial responsibilities whether through institutionalized child-care arrangements, flexible work schedules, or family-related policies. While these conclusions are certainly not new, Lopata's book provides a terrific overview of the existing literature on women's varied roles in U.S. society and how these roles shift and change over the life cycle. As such, this is a fine book, a valuable resource for graduate students and a useful text for undergraduate courses on the sociology of family, gender, and the life course.

Instructions to Publishers

1. Complete and file one copy of this form with your postmaster on or before October 1, annually. Keep a copy of the completed form for your records.
2. Include in items 10 and 11, in cases where the stockholder or security holder is a trustee, the name of the person or corporation for whom the trustee is acting. Also include the names and addresses of individuals who are stockholders who own or hold 1 percent or more of the total amount of bonds, mortgages, or other securities of the publishing corporation. In item 11, if none, check box. Use blank sheets if more space is required.
3. Be sure to furnish all information called for in item 15, regarding circulation. Free circulation must be shown in items 15d, e, and f.
4. If the publication had second-class authorization as a general or requester publication, this Statement of Ownership, Management, and Circulation must be published; it must be printed in any issue in October or the first printed issue after October, if the publication is not published during October.
5. In item 16, indicate date of the issue in which this Statement of Ownership will be printed.
6. Item 17 must be signed.

Failure to file or publish a statement of ownership may lead to suspension of second-class authorization.

SOCIAL FORCES

AN INTERNATIONAL JOURNAL OF SOCIAL RESEARCH
ASSOCIATED WITH THE SOUTHERN SOCIOLOGICAL SOCIETY

VOLUME 74: NUMBER 3 MARCH 1996

IN GENERAL

1. Mail manuscripts (5 copies) to: **Social Forces**, Department of Sociology, Hamilton Hall, University of North Carolina, Chapel Hill, NC 27599-3210.

2. The paper must not be submitted to another journal while under review by SF.

3. Enclose a $15 processing fee. Papers are not reviewed until this fee is paid. The fee is waived for papers solely by currently enrolled students.

4. Manuscripts are not returned to authors.

5. Authors transfer copyright to SF. Permission fees for reprint of articles are split between authors and journal.

PREPARATION OF MANUSCRIPTS

SF Form For review, papers may be submitted in the form used by SF, American Sociological Association or other major sociological journals. Authors of accepted manuscripts are responsible for putting them into SF form.

Format, Organization, and Style Submit 5 clearly legible copies on 8 ½ by 11 good quality white paper. Double space typing throughout. For an accepted paper being revised to fit SF style, leave at least 1" margins; do not justify margins if using a word processor.

Order Organize the manuscript in this order: cover page; abstract; text; endnotes; references; tables; figures.

Cover Page Give title; author(s); affiliation(s); and a footnote (*) indicating name and address of the author to whom requests for offprints or other correspondence should be sent ("Direct correspondence to ___") and acknowledgment (if any) of financial or other assistance.

Abstract On a separate page, preceding the text, write a summary, 125 or fewer words (70 or fewer for a Research Note).

Endnotes Use only for substantive comments, bearing on content. Number consecutively from 1, double space, and append on a separate page.

Tables Type each table on a separate page. Insert a location note — "Table 1 about here" — in the text. For substantive footnotes relating to a table or figure use lowercase letters. Use tabs to separate columns.

Figures Must be artist-drawn, camera ready. Do not send original copy with a manuscript submitted for review. For review, figures may be roughly drawn but they must be neat and legible. For footnotes to figures, use same symbols as for footnotes to tables.

Mathematical Symbols (and others likely to be obscure to compositor) Clarify with encircled words written in the margin.

References in Text Indicate sources as illustrated below:

- when author's name is in text — Lipset (1960); when author's name is not in text (Lipset 1960)
- use page numbers only for direct quotations or specific notes or table — (Braudel 1969:213)
- for more than 3 authors use "et al."
- with more than 1 reference to an author in the same year, distinguish them by the use of letters (a,b,c) with year of publication (1975a)
- earlier publication should precede later publication in brackets with parentheses (Tocqueville [1835] 1956)
- enclose a series of references — in alphabetical order — in parentheses, separated by semicolons (e.g., Adler 1975; Adler & Simon 1979; Anderson, Chiricos & Waldo 1977; Bernstein et al. 1977; Chesney-Ling 1973a, 1973b).

References Following Endnotes List authors alphabetically, by surname. Spell out first names of all authors and editors. For authors with more than one work cited, list works earliest to latest. For articles, next give title of article (caps and lower case), name of journal, volume number, and pagination. For books and monographs, give title, followed by publisher.

Format of References Please spell out the first names of all authors and editors, unless they use only their initials or a first initial and a middle name in the source cited (e.g., Paul Radin, T.S. Eliot, and J. Owen Dorsey).

Stratification Dynamics under State Socialism: The Case of Urban China, 1949-1993*

XUEGUANG ZHOU, *Duke University*
NANCY BRANDON TUMA, *Stanford University*
PHYLLIS MOEN, *Cornell University*

Abstract

Previous studies of stratification under state socialism have emphasized the institutional structure of redistributive economies. This article stresses the importance of the state and political mechanisms. We argue that individual life chances under state socialism are extremely sensitive to political processes, especially shifts in state policies, and that changes in state policies can dramatically alter opportunity structures, the status of structural locations, and the nature and value of political and human capital. Therefore, effects of these characteristics on life chances often vary across historical periods and over an individual's life course. Supporting evidence comes from a study of labor force entry and Communist Party membership in urban China from 1949 to 1993 based on life histories for samples of residents in Beijing and Shanghai.

Studies of stratification in industrialized market societies typically focus on inter- and intragenerational social mobility and status attainment (e.g., Blau & Duncan 1967; Breiger 1981; Goldthorpe 1987; Hauser & Featherman 1977). There has been extensive study of the channels of social mobility — the relative contribution to upward mobility of social status inherited from parents versus acquired human and social capital (Hout 1988; Yamaguchi 1983).

The focus on structural conditions, social origins, and occupational position implicitly assumes that the mechanisms of stratification are relatively stable

* *We are grateful to Liren Hou and Lin Lu for their able research assistance. The Sociology Departments at Fudan University in Shanghai and the People's University in Beijing, and, in particular Fan Weida, Li Qiang, Peng Xizhe, and Yan Jialin provided generous assistance with the data collection. We appreciate the helpful suggestions of David Grusky and Andrew Walder. This project has been partly supported by grants from the National Science Foundation (SES-9212936, SBR-9321462, SBR-9413540, SBR9541309), an ASA/NSF grant for the advancement of the discipline, the Halpern Fund, and an L.T. Lam Award from the East Asian Program at Cornell University. The first author was supported by a Spencer Fellowship from the National Academy of Education while working on this research. Send communications to Xueguang Zhou, Department of Sociology, Duke University, Durham, NC 27708, or via e-mail to xzhou@soc.duke.edu.*

across generations and over an individual's life course. In industrialized market societies, patterns of social mobility are relatively consistent over time and place (e.g., Erikson & Goldthorpe 1992; Grusky & Hauser 1984; Hauser & Grusky 1988; Sorensen 1992), even though some cross-national variation in mobility regimes clearly exists.[1] Father's social status and son's education, for instance, have remarkably consistent positive effects on intergenerational mobility over time (see, e.g., Featherman & Hauser 1978; Hout 1988).

Most of the existing stratification literature focuses on industrialized market societies, especially the U.S. While it provides a useful baseline, it has serious deficiencies for understanding stratification in state socialist societies. In these societies, stratification is organized around the state-socialist redistributive economy rather than a market economy. Resource transfers and the location of individuals in the social structure are largely determined by political power rather than by market mechanisms.

In this study we explore the linkage between the state and life chances in urban areas of the People's Republic of China. China is an excellent forum for such a study, not only because of its unique path of economic reform in the last 15 years, but also because of the marked political changes in its 45 years of communist rule. The Chinese experience is invaluable for studying the impacts of a highly volatile political and economic environment on individual life chances. By life chances, we mean events related to an individual's socioeconomic well-being, such as educational opportunities, position in occupational and organizational hierarchies, and political status.

To examine the links between the political dynamics induced by state policy shifts and individuals' lives in urban China, we analyze patterns of labor force entry and the acquisition of an important political status, Communist Party membership. We consider the impacts of not only the common determinants of life chances in industrialized market societies (e.g., social origins, inherited and achieved social and human capital) but also some distinctive factors in state socialist systems, in particular, sudden and sharp shifts in state policy. We use an event history framework to model changes in life chances over time.

Institutional Structure and Stratification

The idea that different political and economic institutions produce different patterns of stratification and inequality is not new. Ivan Szelényi (1978) argued that mechanisms of stratification in state socialist redistributive systems and in market systems differ qualitatively. He showed that in the state socialist system, the redistribution of resources and the allocation of welfare are based on political power, which engenders conflict between "immediate producers" and "redistributors." The linkage between the state and individual life chances has been widely recognized by scholars studying China (Blau & Ruan 1990; Lin & Xie 1988; Parish 1984; Whyte 1985). Titma and Tuma (1993) also called attention to the political construction of opportunity structures in state socialist societies, stressing the importance of the hierarchies of economic sectors (ministries) and of places in the stratification system in the Soviet Union. The central role of the state and of political power as stratifying mechanisms in state socialist societies

leads their labor market structures to differ markedly from those in market societies (Burawoy & Lukács 1985; Connor 1979; Stark 1986).

Consider the socioeconomic status of occupations in Ivan Szelényi's (1978) study of Hungary. Although the occupational categories are similar to those in industrialized market societies (i.e., professionals, managers, clerks, skilled and unskilled workers), the stratification mechanisms differ substantially. The privileges and benefits of various social groups depend systematically on their relationship to the communist state. For instance, the communist state bred a new "bureaucratic class" of redistributors who enjoyed greater political power and a higher socioeconomic status than all other social groups (Bauman 1974; Djilas 1966; Konrád & Szelényi 1979). Although Szelényi discussed Eastern Europe, his argument fits China well (Nee 1989). The dominance of the redistributive system in China parallels that in Eastern Europe, and its bureaucratic class enjoys special privileges and benefits similar to its East European counterparts (Zhou 1995). Walder (1995) also finds that professionals and bureaucratic managers have distinctive career paths.

Recently Lin and Bian (1991) and Walder (1986, 1992) have called attention to another structural feature of stratification under state socialism, the differentiation of organizations based on state socialist property rights. In China, the relations of organizations to the state are hierarchically ordered in terms of property rights, which causes these organizations to differ in political power, economic benefits, and prestige. The organizational hierarchy is a key feature that helps legitimate the state socialist system. As Walder (1986) says: "The extraordinary job security and benefits, the goods and services distributed directly by the state enterprise in a situation of scarcity that affects other sectors of the workforce more severely, is an important source of acceptance of the system" (248).

Since the distribution of resources and welfare occurs mainly through organizational channels, individuals in different types of organizations have different career trajectories, promotion opportunities, and other life chances.[2] Those working in government agencies, for instance, have not only authority over those in other types of organizations but also better access to housing, hospitals, and so on. Lin and Bian (1991) found that urban China has a segmented labor structure based on the organizational hierarchy and that this hierarchy significantly affects status attainment. Even for workers, social status depends on the property rights relation of their organization to the state. Workers enjoy better welfare programs in state-owned enterprises than they would in the collective and private sectors (Bian 1994; Walder 1992).

The Dynamics of Social Stratification

Although the unique institutional structure in state socialist societies is important, an emphasis on structural conditions alone is incomplete for understanding stratification in these societies. In contrast to industrialized market societies, in China the structural conditions — occupational and organizational hierarchies — are subject to change, especially to political changes directed by the communist state and implemented in state policies.

Stratification under state socialism is constructed through a top-down process. Hence, the impact of political change on individual life chances depends on both the scope and timing of state policies.

The broad scope of the socialist state's power over all areas of social life distinguishes it from other powerful and repressive states that nonetheless have relatively small effects on individuals' everyday lives. From income distribution, to housing, to various welfare programs, almost all life chances of individuals and social groups in China are under the distributive power of the state (Walder 1986; Whyte & Parish 1984). Equally critical is the timing of state policy shifts. Given monopolistic power concentrated in a few leaders, the communist state can transfer resources from one sector to another relatively quickly, either in response to emerging crises or in pursuit of the leaders' goals. Consequently, the macropolitical process is often characterized by sharp political twists and turns in state policies.

To the best of our knowledge, Davis (1992a, 1992b) conducted the first elaborate and systematic study in urban China of the inconsistent paths of individuals' lives resulting from political changes. She demonstrated that downward mobility of the children of the urban "middle class" during the Cultural Revolution was largely due to shifts in state policies. Similar patterns have been observed in other state socialist societies. For example, Szelényi and Manchin (1987) noted that the state's repressive policy of collectivization interrupted embourgeoisement in rural Hungary in the earlier period and called explicitly for a "life history" perspective to study it (see also Szelényi 1988). However, the structural conditions of state socialism have overshadowed the dynamic aspects in most of the existing literature.

Social positions are associated with different political, ideological, and economic resources. Stratification structures channel resource transfers across generations and over stages of an individual's life course. Weber (1978) views the stratification structure as ultimately resting on market position: "The kind of chance in the *market* is the decisive movement which presents a common condition for the individual's fate. Class situation is, in this sense, ultimately market situation" (928). Thus, to understand stratification from a comparative perspective, one needs to understand differences in market and redistributive mechanisms in transferring resources across generations and in allocating resources among social groups

In a market economy, political and economic transactions are based on the principle of *exchange* (Lindblom 1977). In this institutional structure, initial endowments of resources have a lasting effect on social position because private property rights prevail and stabilize the relative opportunities of various groups based on their preexisting social and economic resources. Not surprisingly, then, until very recently social mobility and stratification in industrialized market societies have been characterized by persistent advantages of initial resource endowments. Studies invariably find that social mobility in industrialized market societies mainly operates through individual and family-based social inheritance and achievement. Improvements in socioeconomic status have largely resulted from the emergence of new opportunities due to industrialization and concomitant structural changes (Treiman 1970). The implication for

individual life chances in market systems is a high degree of stability of the relative social status of social groups.

Mechanisms of resource transfer in state socialist societies are qualitatively different. Under state socialism, boundaries and the relative positions of social groups (classes), organizations, and localities are based on state policy considerations rather than market transactions (Zhou 1993). As a result, social boundaries are fluid and vulnerable to state policy shifts. In tandem with state policy shifts, resources are redistributed across sectors, and the life chances of social groups and individuals in various social sectors change. In sum, macropolitical dynamics decisively and directly affect life chances of social groups and individuals in China, regardless of their structural locations.

Specifically, we point to two distinctive effects of state dominance on patterns of stratification. First, the state may alter the relative socioeconomic status of social groups by drastically shifting their relative resources. Such resource transfers are typically based on ideological and political considerations rather than on market efficiency. During the 45 years of communist rule in China, state policies have changed frequently and substantially, for example, between political control and economic development, between competence and political loyalty in criteria for promotion, and between centralization and decentralization in administrative structure (Nathan 1976; Zhou 1992). Drastic shifts in the relative status of social groups have resulted. For example, state policies that redirected resources to children of the working class (e.g., educational opportunities and recruitment into the Communist Party and into higher-status organizations and jobs) substantially changed patterns of social mobility in China (Parish 1984). It should be noted, however, that the state policy of discriminating against certain classes was officially discontinued in 1979.

Second, in a politicized society, the symbolic boundary between "us" and "them" is critical, and shifts in state policies often redraw such boundaries. Indeed, state policies may change the very meaning of "resources," thus altering the nature of social inheritance. For example, education was a political liability rather than a resource during the Cultural Revolution, and white-collar occupations have not consistently delivered the economic benefits and prestige common in other societies (Davis 1992a). Thus, to understand resources associated with positions in the social structure requires substantive interpretation of the historical context.

Consequently, we expect that the distribution of opportunities in China varies systematically with shifts in state policies. State policy shifts often expand or reduce the opportunities in ways that affect all social groups and individuals simultaneously. In all societies, external shocks (e.g., economic crises, war, natural disasters) adversely affect all social groups, but the extent varies due to social differentiation of groups (Elder 1974). In China, drastic changes in overall opportunities have often been due to disastrous state policies. As a result, their effects have been greater, less predictable, and more uniform. Parish (1984) demonstrated the systematic effort of the Chinese state to pursue an egalitarian society during the Mao era. Similarly, in discussing the "politics of life chances" in China, Whyte (1985) traced four historical periods under communist rule and observed that state policies tend to affect all social groups in comparable ways. Sometimes they raise the general level of economic development and opportuni-

ties, as occurred during the first period, the 1950s, when expansion of the state and the economy created more opportunities and widespread upward mobility. Contrarily, policy disasters (e.g., the Great Leap Forward and its aftermath in 1958-62) reduce living standards and economic development and adversely affect the life chances of individuals across organizational and occupational boundaries.

In addition, we think that effects of individual attributes on life chances vary over time. The literature on stratification dynamics in industrialized market societies rests on the assumption that human, social, cultural, and political capitals (e.g., parental socioeconomic status, education, political affiliation) invariably have positive returns and enhance individuals' upward mobility. Chinese political dynamics imply that conventional capitals embedded in individuals do not have consistent impacts on life chances over time: In the Chinese experience, today's capital may become tomorrow's liability.

Consider education as an example. In industrialized market societies, education contributes significantly to individuals' upward mobility (Blau & Duncan 1967; Hout 1988). In China, however, the effect of education on individuals' life chances has varied dramatically depending on current state policies (Kraus 1981; Rosen 1982; Unger 1982). In the early years of communist China, the Communist Party stressed candidates' "revolutionary experience" (Lee 1991) and downplayed education. During the Cultural Revolution, Maoist leaders treated intellectuals with suspicion and hostility and made serious attempts to recruit those with peasant or worker backgrounds into management positions, viewing them as supportive of the radical political cause (Whyte 1973). In the post-Mao era, education has again become important for upward mobility. The new cadre policies adopted in 1980 emphasize educational qualifications and competence in recruitment and promotion (Lee 1991). In a fluctuating environment, human, social, and political capital do not necessarily accumulate and give consistently positive returns.

In a similar vein, we also think that the effects on life chances of structural position in the occupational and organizational hierarchies vary over time. As noted above, the occupational and organizational hierarchies in China are constructed by political processes. In contrast to the gradual expansion of opportunities with industrialization in market societies, shifts in state policies in China dramatically alter life chances of social groups from time to time.

For instance, the social status of occupational groups is politically constructed in accord with official class identification in Communist ideology. The high political status of industrial workers (*chanye gongren*) was not based on their prestige or income but on ideological considerations of the communist state. But as a political construction, the status of occupational groups is sensitive to state policy shifts (Xiao 1989). Workers were favored in Mao's era but their political status declined substantially during the reform era. In contrast, intellectuals had low status in Mao's era but a higher status in the reform era. Similarly, although the organizational hierarchy has been relatively stable over time, its effect on life chances has not been constant. During the Cultural Revolution, individuals in all kinds of organizations experienced similar dislocations. These dramatic changes across historical periods suggest nonmonotonic effects of structural conditions on individual life chances.

In sum, our discussion points to the crucial importance of the *dynamics of stratification* under state socialism. By this term we mean the patterns of change in stratification structures (e.g., in the location of boundaries, in relative rankings of social positions) and in the mechanisms of stratification. Our central argument can be summarized as follows: Life chances under state socialism, in contrast to industrialized market societies, are affected not only by the distinctive structural conditions of the state redistributive system (the occupational and organizational hierarchies), but to a much greater extent by political dynamics and concomitant shifts in state policies that directly and immediately alter the opportunity structure and the value of various social resources for individuals' life chances. Political dynamics are not irrelevant to life chances in industrialized market societies, but shifts in opportunity structures and mechanisms evolve much more slowly and smoothly in such societies, making it possible to focus on structure alone in most analyses of industrialized market societies.

Data

Our empirical analyses are based primarily on life history data for a sample of 1,038 urban residents in Beijing and Shanghai. The data were collected in the summer of 1993 by interviewers using a pretested questionnaire. The questionnaire collected life history data on the respondent's shifts across organizations, occupations, and geographic locations. We also asked about family background, family structure, and political status over time, as well as income and housing conditions in selected years.

Since we collected the data retrospectively, errors in recalling events are inevitable. An advantage of collecting event history data in China is that individual job mobility was severely limited before the economic reforms in 1979; hence respondents did not need to recall many changes. Mobility has increased considerably in the last decade, but recent events are likely to be recalled fairly accurately. All in all, errors from collecting the data retrospectively are likely to be less serious in China than in some other societies.

We used a multistage sampling scheme to draw our sample in the two cities. In China, a metropolitan city is composed of residential districts. Each district is composed of residential "streets," within which households are organized into residential blocks (*Juweihui*). In each city we selected first residential districts and then residential blocks based on their proportion of residents, according to official statistics provided by the municipal government. To select households within each residential block, we used a systematic random sampling procedure; that is, we chose every *n*th household. In all, we chose 1,300 households in a total of 75 residential blocks in six districts. Finally, a member of the household between ages 25 and 65 was chosen for the survey using a random number table. Respondents included both current labor force participants and retirees. We successfully completed 1,038 interviews, giving a response rate of 80%. Interviewers rated almost all respondents as cooperative.

We note that the two cities are not representative of urban areas in China. Beijing, the political capital, and Shanghai, the largest industrial center in China, certainly have enjoyed better opportunities than other urban areas. Moreover,

in a highly centralized political system like China's, state policies can produce marked variations among both regions and urban areas. Therefore, our analyses provide only a glimpse of the dynamics of stratification in urban China. Nevertheless, given the strong grip of the socialist state, changes in life chances across urban areas in China are likely to be much smaller than those in a market economy. Therefore, we believe the results of our analyses are indicative of the overall patterns in urban China.[3]

Variables

Our discussion of stratification dynamics under state socialism points to varying mechanisms of stratification, on the one hand, and varied opportunities contingent on state policy shifts over time, on the other. Along these lines, we consider three dependent variables (first entry into an occupation, first entry into a type of organization, entry into the Communist Party), three main independent variables (human capital, political capital, historical periods), and three control variables (gender, place, age).

DEPENDENT VARIABLES

Occupation

We used the following occupational groups, ordered according to their hierarchical position in the state socialist redistributive system: (1) Cadres include those in managerial positions in enterprises as well as cadres in party and government agencies. (2) Professional jobs are occupations similar to those in industrialized societies, such as university faculty, teachers, and researchers. (3) Workers include all types of workers (including those in services and transportation), regardless of their position in the organizational hierarchy. (4) Farmers (peasants) in these two cities are comprised mainly of the "sent-down" youth who later returned to their original urban areas. Due to the rarity in our sample, we treated entry into two other occupations, self-employed entrepreneurs and clerical workers, as censored observations in our analyses of entry into an occupation, thereby avoiding the biases that would result from simply dropping them from the analysis.

Type of Organization

Our measures of organizational type are based on two dimensions: social-political status and the vertical property-rights relation to the state. We distinguish the following types of organizations,[4] listed roughly in descending hierarchical order:

(1) Government agencies (*zhengfu Jiguan*) include ministries, commissions, bureaus, and offices at various levels of the Communist Party and of state bureaucracies. Both the Communist Party and the administrative apparatus, which are interwoven at every level, belong to this category. Government agencies participate in making and/or implementation of state policies.

(2) Public organizations (*shiye danwei*) are nonprofit organizations in the public domain. They include educational and research institutions, and

organizations in the medical, publishing, broadcasting, and entertainment sectors. Although not administrative organs of the state, most of these organizations are closely linked with the state or with local governments in two respects. First, these organizations are financed directly by the governmental budget; secondly, the personnel systems in these organizations are under the same administration of the central government as those in government agencies. For instance, educational institutions are financed by the central or local government and their personnel system is directly subject to the regulation of the corresponding government agencies. Until recently, under the central planning system, those employed in government agencies and those working in public organizations were covered in the same salary system. That is, employees in both types of organizations had the same opportunities for salary increases. Certain types of public organizations, such as elementary and junior high schools, may not be as favorable in terms of welfare as some state-owned firms. Overall, however, public organizations as defined here enjoy higher socioeconomic status under the state redistributive system.

(3) State-owned firms (*guoying qiye*) include work units in manufacturing, processing, and other production areas, as well as ones in service sectors owned by central or municipal governments. These organizations enjoy extensive welfare programs in housing, health care, and welfare subsidies.

(4) Collective firms (*jiti qiye*) are firms not directly under the administration or financial support of central planners, though they are often sponsored by a local government (e.g., a district or county government or residential office). This type of organization offers the least desirable welfare programs and had low social status in urban China until very recently.

(5) Villages or people's communes in rural areas are included as a type of organization because they were the main destination of "sent-down" youth during the Cultural Revolution.

Party Membership

Respondents were asked if they had ever joined the Communist Party and, if so, in what month and year they had joined.

INDEPENDENT VARIABLES

Human Capital

We follow convention and measure human capital by educational attainment. Educational level is classified in terms of: (1) college (including *dazhuan* and graduate programs); (2) high school (including technical high school, *zhongzhuan*); (3) junior high school; and (4) elementary school or below. We collected information on both the timing and level of educational attainment.

Political Capital

In China, "family background" *(jiating chushen)* refers to the Communist Party's grouping of individuals into different classes according to their family roots. Although highly correlated with father's socioeconomic status, "family background" is not the same as father's occupation currently or at age 14. Rather, it

refers primarily to the *class* position of the father or grandfather before 1949.[5] We use "family background" instead of the conventional father's social status because this politically defined category has been an important criterion in job assignments and promotions.

Based on our knowledge of this political construction, we classified family background into the following four categories of descending status: (1) The *cadre class* refers to those whose parents are cadres. This group has been argued to enjoy special political privileges under state socialism. (2) The *working class* includes adult children or grandchildren of workers or poor peasants; it is the group that the Communist Party proclaimed to be the cornerstone of communism. (3) The *"distrusted" class* includes those parents or grandparents who were small business owners (*yezliu*) or middle peasants (*zhongnong*), as well as those whose parents or grandparents were landlords or large business owners (*zibenjia*).

Historical Periods

Our discussion of the processes of stratification in China implies strong period effects, which are highly associated with state policies and which indicate the overall level of opportunities for all social groups (Whyte 1985). We identify three broad historical periods: 1949-65, 1966-79, and 1980-93[6] and discuss the historical context in these periods in the next section.

Control Variables

Control variables include gender (a dummy for being female), place (a dummy for Beijing rather than Shanghai), and age (measured in years minus twenty).

Given the nature and scope of our theoretical concerns, we analyze data only on individuals who entered the labor force after 1949. Cases with information missing on any covariate in a particular model are omitted from that specific analysis. The number of cases dropped because of missing data is very small. In analyses of entry into an occupation and organization, we included observations only of those older than 13, assuming that labor force entry at younger ages might signal a respondent error. In the analyses of entry into the Communist Party, we excluded observations after the individual had retired from the labor force and before all individuals reached age 17 (because 18 is the minimum age formally allowed for Communist Party membership). We also excluded observations on individuals in the farm and private sectors because these two groups experienced few events and are substantively different from the reference category of workers.

Models and Methods

We use event history analysis (Tuma & Hannan 1984) to examine individual life chances, life-course trajectories, and rates of transition among differentially ranked social positions. An important advantage of event history analysis is that information on previous life history and on time-varying covariates can be incorporated in analyses of the time-dependent rate of occurrence of various life events.

The general modeling strategy is as follows. Suppose there are data on a sequence of life events over time, such as enrollment in educational institutions, assignment to a particular type of occupation and organization, promotion, and so on. Observed events are regarded as realizations of a latent, random process of change in individual life chances that depends on covariates of theoretical interest, x(t), which may change over time. Following Tuma and Hannan (1984), we define instantaneous transition rates as follows:

$$r_{jk}(t \mid w_{n-1}) = \lim_{\Delta t \downarrow 0} \frac{q_{jk}(t, t + \Delta t \mid w_{n-1})}{\Delta t}$$

where $r_{jk}(t)$ is the instantaneous rate of transition from status J to status k at time t, $q_{jk}(t, t + \Delta t)$ is the probability of a transition from j to k between time t and $t + \Delta t$, and w_{n-1} is the previous history. Since we examine the first event, the number of the event, n, is 1 in our analyses, and previous history refers to the individual's family background.

Our argument about inconsistent effects of human and political capital over time implies a need for models that allow the effects of the covariates of theoretical interest to vary across historical periods. For this purpose, we use piecewise exponential models that allow intercepts and effects of covariates to vary across historical periods:

$$\log r_{jkp}(t) = \beta'_{jkp}\, x(t)$$

where the subscript p denotes a given historical period (e.g., 1949-65, 1966-79, or 1980-93), and $x(t)$ refers to the set of explanatory and control variables used in the analysis. We note that the values of some variables (in particular, age and educational level) change over time for a given individual. In the analysis of entry into the Communist Party, employment status (organization and occupation) also changes over time.

We estimated models by the method of maximum likelihood, which lets us test nested models using likelihood-ratio χ^2 statistics (Tuma & Hannan 1984). The standard errors of parameters in a correctly specified model are asymptotically normally distributed, which lets us test hypotheses that any given parameter in the model differs from some prespecified value (usually zero).

In some analyses we constrain the coefficients of x(t), except for the intercepts, to be the same in every historical period; we denote this as "model A." In other analyses, we let all parameters vary across the historical periods; we call this "model B." Since model A is nested within model B, we can compute a likelihood ratio χ^2 statistic to test whether the effects of covariates vary significantly across the historical periods.

Results

We argued above that shifts in state policies can affect individual life chances in several conceptually distinct ways. First, state policy shifts can directly alter the opportunity structure — the distribution of various resources, social positions, and rewards. The state can expand or reduce access to certain educational levels, occupations, organizational types, and political positions, such as

membership in the Communist Party. In addition, the state can change the criteria used in allocating people to various social positions, as well as alter the political and social status of different social groups. This consequence of state policy changes is the main concern of our research. Finally, via the previous two effects, state policy changes can indirectly induce effects on the composition of the labor force, and thereby amplify or dampen the impacts of other changes. In trying to understand the relationship between stratification and political dynamics, one needs to take all sources of change into account. Below we summarize what we have learned about each source of change based on available public documents and our survey data. Given our emphasis on the fluctuating political environment and state policies, we begin by introducing the historical context of state policy shifts and then describe the evolution of opportunity structures in urban China.

STATE POLICIES AND THE HISTORICAL CONTEXT

Since the establishment of the Communist government in China in 1949, Chinese political and economic structure has been based largely on a Soviet-style party-state. China experienced increasing expansion of the central government and the elaboration of socialist redistributive system (Whyte & Parish 1984). In the 45 years of Communist rule, however, China also experienced frequent and large-scale political and economic changes induced by drastic shifts of state policies. The Anti-Rightist Campaign of 1957, the Great Leap Forward in the late 1950s, the Cultural Revolution, and the recent economic reform are well-known examples. These large-scale socioeconomic changes have had profound impacts on the redistribution of opportunity among social groups. To explore the effects of political dynamics on life chances, we distinguish three broad historical periods that characterize drastic shifts in state policies.

The period 1949-65 was one of nation building and economic development. The Communist government centralized resources and its power through collectivization and nationalization, especially in urban China (Whyte & Parish 1984). During this period, state labor policies were largely geared toward industrialization and economic development, leading to overall expansion of opportunities, but there were notable political fluctuations and political campaigns (Whyte 1985).

The period 1966-79 was the period of the Cultural Revolution and its immediate aftermath. There were not only large-scale political purges and repression, but labor force participation and other opportunities that were highly politicized and severely affected by sharp shifts in state policies. In particular, political standards became the main criterion for job allocation, promotion, and the distribution of resources among social groups. During most of this period, regular promotions and wage increases were frozen.

The period 1980-93 is the post-Mao era when most policies adopted during the Cultural Revolution have been reversed and various reforms have been introduced, especially in urban areas. The economic reforms in this period introduced market mechanisms in resource allocation and created new opportunities, leading to the erosion of the redistributive state (Nee 1989, 1991).

However, since the reforms did not begin in urban areas until 1985 and happened erratically, except in some coastal areas, the effects of an emerging market on labor force participation have been limited in urban China.

CHANGES IN THE OPPORTUNITY STRUCTURE

We have argued that individual life chances vary over time in response to altered opportunity structures resulting from shifts in state policies. The historical patterns of educational and labor force participation, of labor force entry, and of joining the Communist Party provide some evidence that supports our argument.

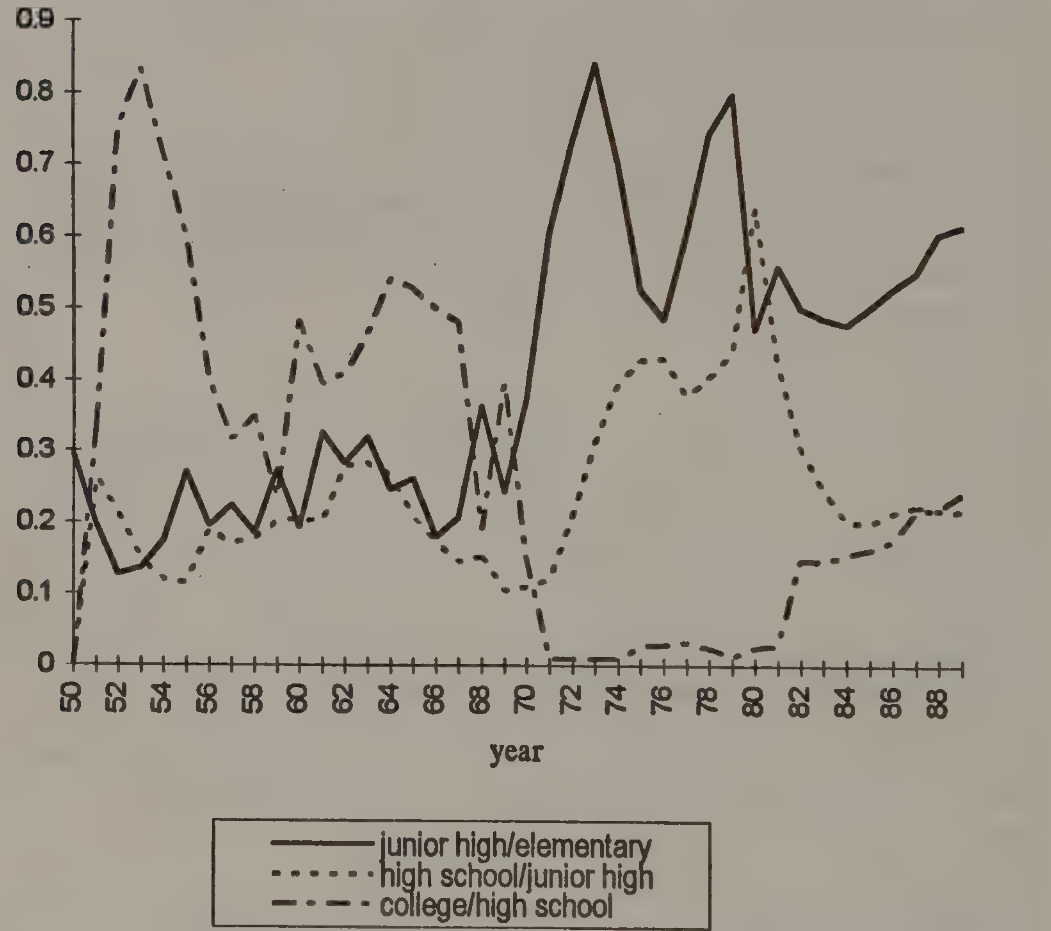
Educational Opportunities

Figure 1 shows the number of graduates at each educational level divided by the number at the level just below it by year for 1949-89.[7] It provides evidence that educational opportunities in China have varied across historical periods in accordance with state policies. First, the proportions of high school and college graduates were extremely low during the earlier years of the Cultural Revolution when radical state policies severely disrupted the educational sector. Second, the extremely low proportion of college graduates from 1971 to 1981 resulted directly from state policies that closed colleges during the early years of the Cultural Revolution. In fact, no high school graduates, regardless of their social origins, were directly admitted to college from 1966 to 1978. The first cohort of college students after the Cultural Revolution did not graduate until 1982.

Labor Force Participation

Figures 2 and 3 show the labor force composition from 1949 to 1989 in Beijing and Shanghai, respectively (China State Statistics Bureau 1990). (Private entrepreneurs are not displayed due to their small numbers.) A comparison of the two figures reveals a striking similarity between the two cities over time. Such similarity indicates the impact of state policies. For instance, the policy to incorporate private enterprises into state-owned ones after 1956 led to a sharp rise in employment in the state sector. Similarly, the economic crises of the early 1960s led the government to force large numbers of workers to return to rural areas; it is reflected in a sharp decrease in employment in the state sector in the early 1960s. In 1968, Mao Zedong and the Communist leadership instituted the "send-down" policy, which forced junior high and high school graduates (the "educated youth") to the countryside. Between 1968 and 1979, over twenty million educated youth were sent to rural areas to work as farmers. Roughly a half returned to urban areas before 1978, and the rest mainly returned by the end of 1979, when the original policy was denounced (Deng 1993). Note that the proportion of the labor force in state sectors compared to that in the collective sectors is relatively stable, even in the post-Mao era.

FIGURE 1: Ratio of Graduates from Each Educational Level (By Year)



Changes in Access to a First Occupation and First Organization

We next consider changes over time in work opportunities as estimated from the data on our sample. We consider access to a first occupation and a first organization in the three historical periods. One of the most revealing statistics for this purpose is the overall annual rates of entry into various occupations and organizations in the three historical periods, which are reported in Table 1.

The annual rates given in this table clearly indicate that opportunities have changed markedly across historical periods. First, there is evidence of long-term trends in industrialization and economic development: The rates at which labor market entrants become workers and professionals are much higher in the 1980-93 period than in 1949-65. Correspondingly, the rates of entering public organizations (where many professionals work) and state-owned firms are also markedly higher in 1980-93 than in 1949-65. The rate of labor market entrants entering a government agency also grows substantially, but more modestly. These shifts reflect the political leadership's renewed concern for economic expansion after the Cultural Revolution.

However, not all changes in work opportunities can be explained by economic development. For most occupations and organizations, changes over time show no clear trend. In terms of entry into an occupation and organization,

TABLE 1: Structure of Opportunities by Historical Period: Entry Rates per Year for First Occupation, First Organization, and the Communist Party

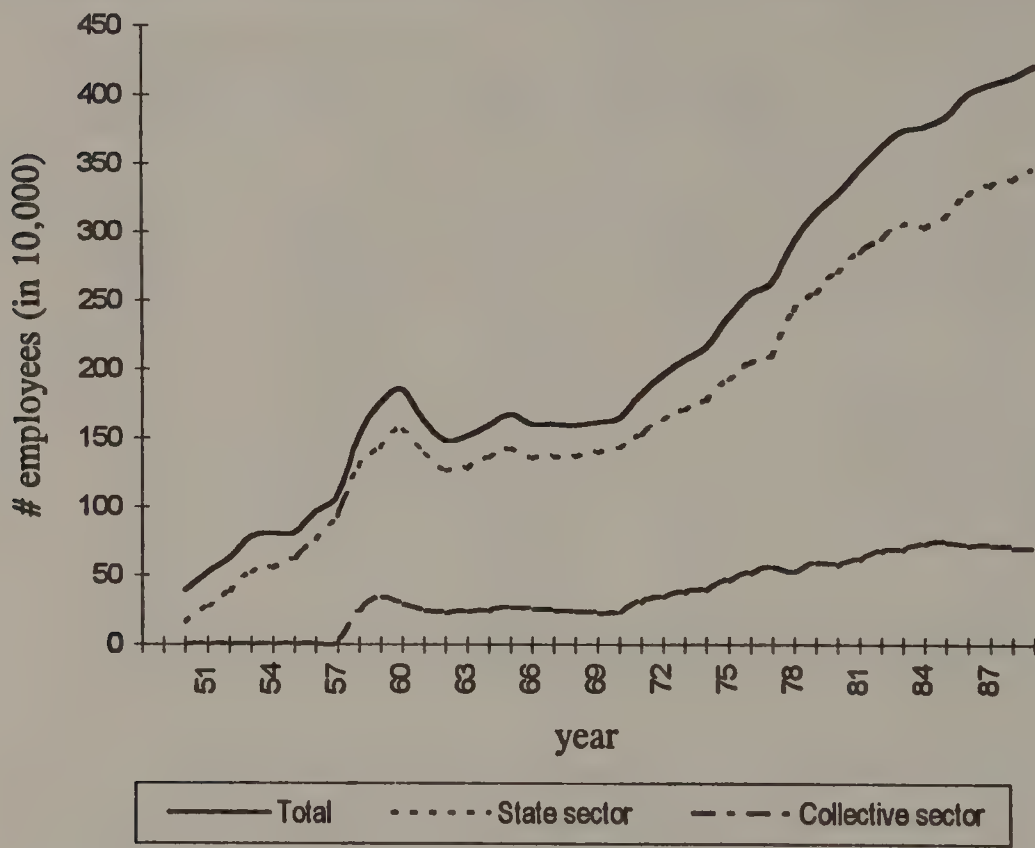
	All Years	1949-65	1966-79	1980-93
Occupation				
Cadre	.016	.018	.014	.016
Professional	.025	.024	.013	.060
Worker	.082	.066	.089	.106
Farmer	.018	.002	.044	—
Type of organization				
Government agency	.018	.019	.013	.024
Public organization	.025	.025	.014	.051
State firm	.068	.054	.068	.107
Collective firm	.015	.010	.020	.020
Village	.018	.002	.044	—
Communist party	.009	.013	.009	.007

the distinctiveness of the Cultural Revolution (1966-79) is striking. It is the only period with nonnegligible rates of labor market entrants becoming farmers and moving to a village type of organizations.[8] This period is also noteworthy for lower rates of labor market entrants obtaining a high-status job — becoming a professional or (to a lesser extent) cadre — and for moving to a government agency or public organization. These changing patterns across historical periods undoubtedly reflect the radical policies introduced during this period.

Changes in Access to the Communist Party

We next consider access to membership in the Communist Party, a very important political resource for people living in urban China. The findings based on our data, shown in the last row of Table 1, are somewhat surprising: Rates of entry into the Communist Party fall steadily across the three historical periods — the rate in the 1980-93 period is about one-half that in the 1949-65 period. One must be careful in interpreting this decline. A falling entry rate does not necessarily mean that the proportion of the population belonging to the Communist Party falls. The rate in the early period may have been unusually high simply because the Communist Party had relatively few members in 1949 and sought to enhance its legitimacy by expanding its membership rather quickly. After the initial rapid expansion, fewer new members were needed each year to maintain a steady size since membership in the Communist Party is usually for life. Still, the decrease means that later cohorts had less access to this important political resource than did earlier cohorts who were eligible to join the Party in the early years of the communist state.

FIGURE 2: Labor Force Composition in Beijing, 1949-1989



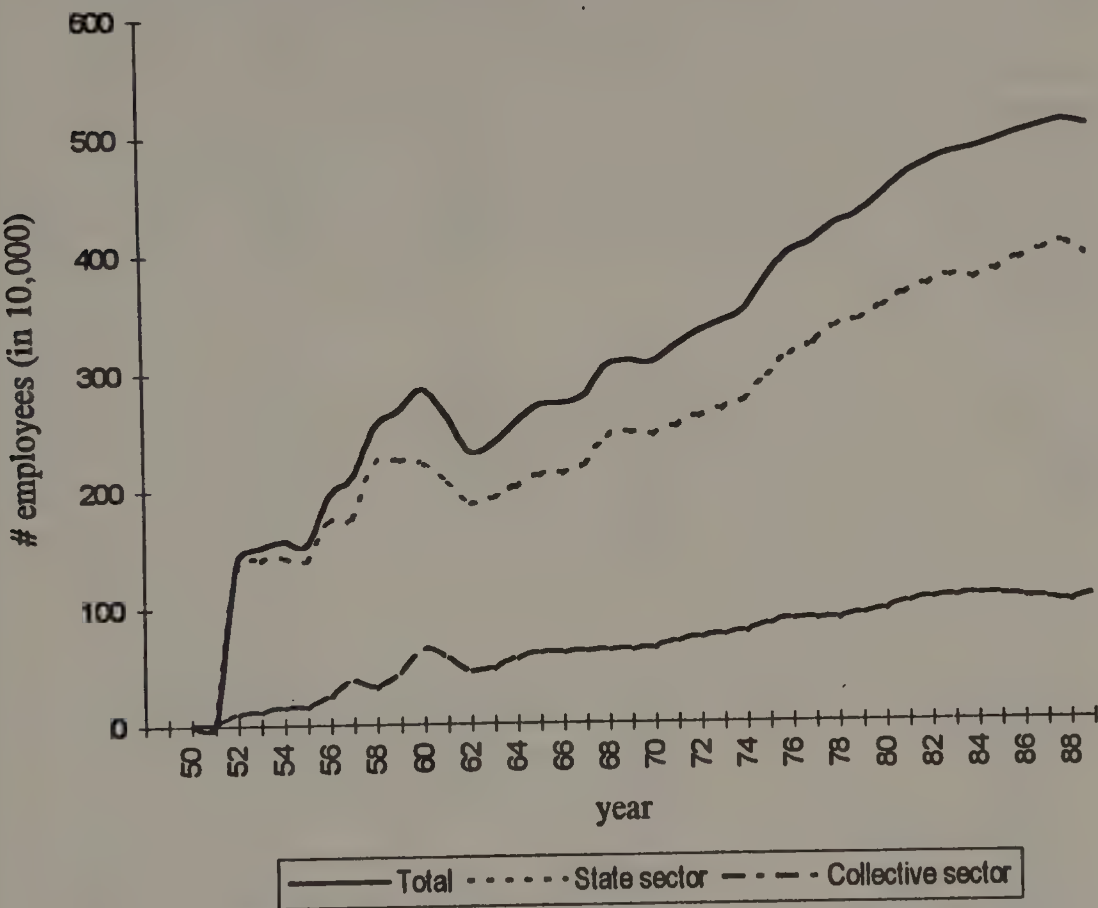
Summary

Overall, changes over these three historical periods in educational and labor force participation and in the entry rates reported in Table 1 reveal major variation in the opportunity structure in urban China during this 45-year period. The differences in opportunities in various occupations and types of organizations during the Cultural Revolution are so sharply different from any trend expected because of economic development that it is reasonable to attribute them to shifts in state policies. The conclusions are obvious: Changes in opportunity structures directly affect the distribution of life chances for individuals who entered the labor force in a particular historical period

Changes in Composition of the Population

Using data on our samples in Beijing and Shanghai, we next consider cross-period variation in key characteristics of the populations at risk of entering various positions in the main social hierarchies (see Table 2).[9] The variation in the population's composition are indicative of the consequences of the twists and turns in state policies in urban China.

FIGURE 3: Labor Force Composition in Shanghai, 1949-1989



Composition of Population at Risk of Entering the Labor Force

Clearly, the composition of people at risk of entering the labor force (shown in the top half of Table 2) changes strikingly over time. The period of the Cultural Revolution stands out. Among those at risk of entering the labor force, the proportion of college graduates and the average age are lower in 1966-79 than in the other two periods. These two compositional changes are not unrelated. The closing of colleges and universities and the policy to shorten the time children spent in elementary and junior high school during this period not only reduced the proportion of college attendees and college graduates but also pushed young people into the labor market at younger ages.

Other variations over time in the composition of those at risk of entering the labor force are more subtle consequences of earlier political changes. Following the establishment of communist rule and the concomitant elimination of certain occupations found in the old system and the creation of new occupations (especially cadre), the family background of those at risk of entering the labor force changes dramatically over time. After thirty years of communist rule — that is, since 1980 — most young labor market entrants had parents who acquired positions under the communist system. Consequently, by the 1980-93 period, the proportion with a distrusted family background has shrunk

TABLE 2: Means of Covariates for Risk Sets by Historical Period

	1949-65	1966-79	1980-93
Entry into the labor force			
Education

Beijing	.56	.45	.44
Number of individuals at risk	367	695	831

[a] Distribution excludes those who have not yet entered the labor force.

enormously, while the proportion with a cadre family background has grown greatly. Note that the great growth in a cadre family background may be higher in our study cities of Beijing and Shanghai than in other Chinese cities because of the leading role of these cities in China's political and economic system.

The broad expansion over time in the educational level of labor market entrants, which is another result of state policies, is also readily apparent in Table 2. The proportion who have graduated from a senior high school rises steadily, while the proportion with elementary or no education falls markedly. Among those at risk of entering the labor force, the proportion who have graduated from junior high school rises and later falls, as the educational system continues to expand.

Composition of the Population Eligible to Join the Communist Party

Changes over time in the composition of the group at risk of entering the Communist Party are roughly similar to the changes for the group at risk of entering the labor force. However, the changes in the former group are more muted because the population at risk is much larger and much more diverse, especially in age.

Since our analyses of entry into the Communist Party include measures of labor force status (in urban areas), Table 2 reports compositional changes in it as well as education, family background, and our control variables. The two largest changes are in average age and in the proportion who have not yet entered the labor force. The former is largely a result of our sample design. Many people who were at risk of joining the Communist Party in 1949-65 were no longer living in 1993 or older than 65, the upper age limit for selecting the sample. Given the relative youth of this group in 1949-65, the very high proportion who have not yet entered the labor force during this period is less surprising. It may also be unusually high in 1949-65 because many women did not participate in the paid labor force period to 1949. Even with these two cautionary notes, the change over time in average age and in the proportion who have not yet entered the labor force is striking.

The proportion of those in the labor force who are in various occupations does not change much across the three periods, although the proportion who are soldiers falls markedly and the proportion who are workers or in other, peripheral occupations rises correspondingly. The proportion of those in the labor force who are in various types of organizations changes somewhat more, with the fraction working in a government agency falling and the fraction working in collective and state-owned firms rising slightly.

CHANGES IN ALLOCATION CRITERIA

An important aspect of stratification dynamics lies in the changes in allocation criteria that result over time from shifting state policies, the topic of our next set of analyses and a major focus of our research. In considering this topic, we stress that as a consequence of revisions in state policies, the prestige and other social rewards of occupations and organizations in China varied across historical periods, as we described earlier. We should bear these contextual variations in mind in interpreting the statistical results.

As we indicated in describing our methods, to examine changes in allocation criteria across historical periods, we estimated piecewise exponential models of entry into first occupation, first organization, and the Communist Party. For each outcome, we first estimated a model that constrains the covariates to have the same effects in all three historical periods but lets the intercept vary across periods. This model, denoted model A, provides the baseline for examining our argument that the effects of the covariates (i.e., allocation criteria) vary across the three periods. Our argument that the criteria do change over time is represented by a model in which effects of the covariates as well as the intercepts can vary across the historical periods; it is denoted model B. Note that time variation in the values of variables and time variation in their effects are conceptually different; the former is a feature of the data in all of our analyses.

Because we consider multiple destinations for each outcome in each period, the number of transitions to a given destination in a given period is small, except for workers and state-owned firms, which are the most prevalent occupation and type of organization, respectively. Consequently, the statistical power for testing hypotheses about the effect of a single covariate in a single period is low for occupations other than worker and for types of organizations other than state-owned firms. Hence, we consider the magnitude and sign of effects of theoretical interest as well as their statistical significance. We report the result of a one-tailed test when we have a definite hypothesis about the sign of a covariate's effect, but we mainly use two-tailed tests since most of our arguments admit the possibility that effects actually change sign over time.

Entry into a First Occupation

Table 3 gives the maximum likelihood estimates of the effects of covariates on entry into a first occupation. For each occupation, the first column tells the estimates for model A, and the next three columns give the period-specific estimates for model B.

Both model A and model B significantly improve upon a null model with no covariates and intercepts that can vary across the three historical periods; the probability levels for the likelihood ratio χ^2 statistics for these tests are well below .00001. More importantly, the likelihood ratio test comparing model B against model A is 495.0 with 24 degrees of freedom, which also has a *p* level well below .00001.[10] Thus, we can reject the model of time-invariant effects of covariates on the rate of entering a first occupation with considerable confidence. In substantive terms, this means that the criteria used to allocate labor market entrants to their first occupation do vary across the three historical periods, quite aside from the send-down policy that assigned many urban youth to work as farmers during the Cultural Revolution.

Becoming a Cadre. Consider first the pattern of effects in all years, which gives a kind of "average" effect during the 1949-93 period. Relative to a junior high education (the reference category), having a college education has a significant positive effect on the rate of becoming a cadre, whereas having an elementary or no education has a significant negative effect. The rate of entry into this high-status occupation is significantly lower for females and significantly higher for residents of Beijing; it also rises significantly as age increases.[11]

Central to our theoretical concerns, however, are variations across historical periods. Notice first that the intercept steadily and markedly declines over time. The intercept is the log of the rate for the reference category: 20-year-old, male residents of Shanghai with a junior high education and a working class family background. The decline in the intercepts, especially seen in model B, means that over time, cadre are decreasingly chosen from youth with a working-class family background and a junior high education.

The variation in the effects of education over time are especially relevant to our arguments. The general pattern seen in Table 3 is one of positive and increasing effects of having a college education and of negative effects of having an elementary school or no education. The significant, positive effects of having a college education during 1966-79 seem at odds with the discriminatory policy against intellectuals during the Cultural Revolution. We suspect that this result may be due to the favorable policy toward the "Red Guards," many of whom were college graduates. One cannot put much confidence in the small negative effect of an elementary or no education in the last period because only 6% of the observations at risk are in this educational category in that period, whereas 40% are in this category in the first period. The effects of a college or senior high education are large in the 1980-93 period but do not differ significantly from zero. The lack of statistical significance reflects the very small number of moves directly to the cadre occupation in this period, which is partly due to relatively few people in our sample who are at risk of entering the labor force during this period.[12]

Family background indicates individuals' political and cultural capital. The results in Table 3 indicate that those with a "distrusted" or cadre family background have the lowest rate of entry into the cadre occupation during the Cultural Revolution. Although these effects are not statistically significant, which is at least partly due to the few cases in these categories, their effects are consistent with the dominant state policies in force during this historical period. During the Cultural Revolution, older generations of cadres were purged, and a cadre family background became a political liability rather than a political asset. A "distrusted" family background was also especially stigmatized during this period.

The general impression of patterns of entry into the cadre occupation is that by 1980-93, the most important criterion for selection into this occupation is having a higher education. Again, this pattern is consistent with the new cadre policies that emphasize educational qualifications during the reform era.[13]

Becoming a Professional. Education is also very important for entry into a professional occupation. This finding is not so unusual; the same pattern occurs in industrialized market societies. Table 3 shows that having a higher educational level significantly increases the rate of becoming a professional in all three periods. In the first period, having a senior high education and a college education do not seem to be very differentiated. However, over time, having a junior and senior high school education become more similar, and having a college education makes a greater difference. In part this result probably reflects the changing educational composition: Over time, the pool of highly educated youths becomes much larger and the primary source of professionals. Correspondingly, the effect of an elementary school or no education becomes

increasingly negative — the other side of the same coin. The increasing differences in impact of educational levels over time may also mean that the state increasingly relies on educational credentialing in allocation of youth to their first occupation.

With regard to family background, those with a "distrusted" family background have a higher rate of becoming a professional before and during the Cultural Revolution. We interpret this as indicating that such families were better equipped with human and cultural capital to prepare their children for professional jobs. However, given that professionals were stigmatized during the Cultural Revolution, one should not interpret becoming a professional as clearly advantageous. Lastly, those with a cadre family background have a slightly lower rate of becoming a professional during the Cultural Revolution, when they were more likely to become a farmer.

Becoming a Worker. Overall, education affects the rate of becoming a worker in a way that is basically what we had expected. Having an elementary or no education lowers the rate (relative to a junior high level); college graduates also have a lower rate than those with a junior high education, reflecting the fact that college graduates are mainly targeted on cadre and professional occupations. Having a senior high education has a significant negative effect on the rate of becoming a worker in 1949-65 but a significant positive effect in 1980-93. The reversal of sign across these periods should be interpreted in light of changes in the declining effect of having a senior high education on the rate of entry into professional occupations. It signals a reallocation of senior high graduates from professionals in the early period to workers in the 1980-93 period.

Those with a "distrusted" or cadre family background have a significantly lower rate of becoming a worker in almost every period. The effects are especially large and negative during the 1980-93 period, suggesting that by this period, those with either kind of family background are more likely to enter other occupations. It may well indicate that the worker occupation has lost its high prestige by the 1980-93 period and that children from families who are privileged in the new or old systems avoid becoming workers, ceteris paribus. It should be kept in mind that during the Cultural Revolution, workers were elevated to a high status under Mao's famous banner, "The working class is the leading class." A lower rate of entry into a worker occupation during the Cultural Revolution often meant being forced to the countryside.

Becoming a Farmer. Since becoming a farmer resulted mainly from the radical state policies during the Cultural Revolution, there were insufficient cases to estimate a multivariate model of the rate of becoming a farmer except in the 1966-79 period. Here we find the most striking evidence of inconsistent effects of human and political capital on individual life chances. Every educational level has a significantly lower rate of becoming a farmer than the reference category — a junior high education. Those with elementary school or no education and college graduates had the lowest rates of becoming a farmer. Thus, the send-down policy especially affected the life chances of youth with a junior high education. We should keep in mind, however, that the radical state policies in force at that time also lowered the ceiling on the highest level of education that youth could attain.

Those with a cadre family background had a significantly higher rate of becoming a farmer than those having a working class family background. Those with a "distrusted" family background also had a higher rate of becoming a farmer ($p < .10$ using a one-tail test). Substantively, these results indicate that state policies redrew the boundary between "us" and "them" and thereby drastically altered the life chances of those with the previously privileged cadre family background. This shows that the nature of political capital in urban China varied over time.

Entry into a First Organization

We now turn to the analysis of entry into a first organization, considering especially how the criteria used to allocate youth to a first organization vary across the three historical periods. Our findings are reported in Table 4. In general, the patterns parallel those found in the analysis of entry into a first occupation shown in Table 3. This is not surprising because occupation and organization are strongly, though imperfectly, associated. Many cadres work in government agencies; many professionals work in public organizations; workers are usually in state-owned or collective firms; and virtually all farmers are in villages. Indeed farming and being a villager are so closely associated that we do not report results for entry into a village organization in Table 4 — the results for entering a village are almost identical to those for becoming a farmer that are reported in Table 3.

As in the case of our analyses of entry into a first occupation, both models A and B significantly improve upon a null model with no covariates and intercepts that can vary across the three historical periods; the probability levels for these tests are well below .00001. Again, the more interesting test is the comparison of model B and model A. The likelihood ratio χ^2 value for this test is 141.9 with 64 degrees of freedom, which is significant at the .00001 level.[14] Hence, there is strong evidence that the criteria used to allocate youths to their first organizations varied across these three historical periods.

Entry into a Government Agency. Interestingly, the effects of higher education on entry into a government agency are comparatively small and statistically insignificant during the 1949-65 period but larger and statistically significant (for a high school education) during the Cultural Revolution. This anomaly may be because the purge of cadres in government agencies during the Cultural Revolution led to the recruitment into government of those "Red Guards" who graduated from high school or college since political criteria (e.g., loyalty to the Party) were used to recruit college students during this period. By the 1980-93 period, having a college education has a significant positive effect, indicating that educational credentialing is increasingly used to staff positions in government agencies.

The rate of entering a government agency was higher for those with a cadre family background before the Cultural Revolution but significantly lower during the Cultural Revolution. During this period, those with a cadre family background had a significantly higher rate of becoming a farmer, which is equivalent to a village organization, as we said before. So, to a considerable extent, youth with a cadre family background were redirected from government agencies to villages during this period. Those with a "distrusted" family

+ $p < .10$ * $p < .05$ ** $p < .01$

background have a lower rate of entering government agencies in both the Cultural Revolution and the reform era. We suspect that many of them entered the small private sector.[15]

Entry into a Public Organization. Since professionals are concentrated in public organizations (e.g., research and educational institutions, hospitals, and mass media), the patterns for entering a public organization are, not surprisingly, very similar to those for entry into a professional occupation. Having a college or senior high education increases the rate of entering a public organization, and these effects tend to become larger over time. Contrarily, having an elementary school education or no education lowers the rate of entering a public organization, and this effect also tends to become larger (i.e., more negative) over time.

Interestingly, those with a "distrusted" family background have a higher rate of entering public organizations during the Cultural Revolution. We think that this pattern was mainly due to cultural capital from their family's prior training in the professions. Again, it is important to remember that during the Cultural Revolution, rewards in public organizations were not greater than those in state-owned firms.

Entry into a State-owned or Collective Firm. We find occasional significant effects of education on entry into state-owned and collective firms prior to the reform era, but in contrast to the other kinds of organizations and all occupations, educational level seems to be used less or at least less consistently — in allocating youth to these kinds of organizations.

During the Cultural Revolution, those with a "distrusted" family background had significantly lower rates of entry into state-owned and collective firms, which provided urban job opportunities. Those with a cadre family background have similar patterns.

Summary. Over time, patterns of entry into a first occupation and organization have changed substantially, but not in a straightforward way. During the recent reform era as compared to earlier periods, educational attainment becomes much more important for entry into high-status organizations and occupations. Although this pattern may be partly due to changing mechanisms of stratification accompanying marketization, it is also consistent with new state policies that emphasize educational qualifications in job allocation.

The effects of family background are different during the reform era: Those with a cadre family background have a significantly lower rate of becoming a worker and of entering state-owned and collective firms, suggesting that they again have the political capital to obtain more favorable jobs. Those with a "distrusted" family background have a lower rate of entering all types of organizations during the reform era, suggesting that they are more likely to enter one of the types of organizations we were unable to study, in particular, the private sector. In any case, the effects of class background appear to persist even in the recent economic era, but in ways different from previous periods.

Although the relatively small number of events has constrained our ability to perform powerful statistical tests of the effects of specific covariates, the directions of effects for the theoretically relevant covariates are quite consistent

with the oral histories of those living through the turbulent history of contemporary China.

Entry into the Communist Party

Next we examine the effects on entry into the Communist Party of an individual's human capital, family background, and own structural position in the occupational and organizational hierarchies. Communist Party membership serves as an indicator of acquired political capital because it is a key political asset for upward mobility in communist societies (see S. Szelényi 1987 on Hungary and Walder 1995 on China). In such societies, membership in the Communist Party is often a prerequisite to promotion into bureaucratic positions, especially ones at higher levels. Examining Party membership also has the advantage that information on state policies about Party recruitment is widely available; hence, results can be interpreted more definitively.

Twenty-three percent of the respondents in our sample were Party members at the time of the 1993 interview. This seemingly large percentage may reflect the concentration of cadre and high-status personnel in Beijing and Shanghai, where we collected the data. Nevertheless, the rate of entry into the Communist Party is low in every period, as we mentioned in our discussion of Table 1. These two facts are not inconsistent because a person tends to join the Party for life.

Our archival research found that state policies on recruitment into the Party shifted over time. In the years shortly after 1949, class background was stressed. After the 1957 Anti-Rightist Campaign, intellectuals were treated with suspicion for recruitment into the Party. In 1964, Party members comprised 15% of those working in the industrial and transportation sectors, 15% in the public and educational sectors, but only 2% of college students (Zhao 1987). In the mid-1960s, a new policy emphasizing intellectuals led to a sharp increase in their percentage in the Communist Party. Policy shifted once more during the Cultural Revolution, again favoring those with a working class background. In the post-Mao era, the leadership again stressed recruitment of intellectuals into the Party. Consequently, we expect to find that effects of human capital, family background, and structural position on recruitment into the Communist Party vary over time.

In our analyses of entry into the Communist Party, we used the same indicators of human and political capital and the same control variables (gender, place, and age) as in our analyses of entry into the labor force. Structural position is represented by time-varying (0-1) indicators of occupation and organizational type. For occupation we distinguish among cadre, professionals, soldiers, and others (workers are the predominant group in this residual category). For organizational type, we distinguish among government agencies, public organizations, collective firms, and others (state-owned firms are the predominant group in this residual category). We also include a time-varying (0-1) indicator of whether the person has not yet entered the labor force to avoid confounding the reference categories of occupation and organization with having no labor force status at all. Table 5 reports the results of our analyses.

First, we note that both model A and model B significantly improve upon a null model in which the covariates have no effects ($p < .00001$). In addition, a

Model A vs. baseline	254.6**			
Degrees of freedom	15			
Model B vs. Model A			72.5**	
Degrees of freedom			30	
Number of individuals = 974				

[a] Model A has time-varying intercepts, which are listed under the historical period for which they apply. Effects of covariates are time-invariant and are listed under "All Years."

[b] Model B has time-varying effects of covariates, as well as time-varying intercepts. Time-varying parameters are listed under the historical period for which they apply.

+ $p < .10$ * $p < .05$ ** $p < .01$

test of model B versus model A has a likelihood ratio χ^2 value of 72.5 with 30 degrees of freedom, which is statistically significant at the .0001 level. Thus, there is clear evidence of time variation in effects of the covariates on entry into the Communist Party.

Both structural position and human capital have some time-varying effects on Party recruitment. With regard to organizational type, working in a government agency increases the rate of joining the Party relative to the reference category (predominantly, working in a state-owned firm) in 1949-65, but it has an insignificant effect in subsequent periods. Working in a collective firm has a negative effect in every period, but it never differs significantly from the reference category. In contrast, the rate of joining the Party is significantly higher ($p < .10$ using a one-tail test) for those working in a public organization than in a state-owned firm only during the Cultural Revolution (1966-79). This finding probably reflects the politicization of the public sector (e.g., educational institutions, the media) during that period.

As for occupation, consistent with state policy, professionals had a significantly lower rate of becoming a Party member during the first period as compared with the reference category (predominantly workers). The rate of joining the Communist Party is higher for the cadre category than for the reference category in every period, though the difference in the first period is not statistically significant nor as great as in the later periods. This pattern suggests that cadres were recruited into the Party in every period, though especially after the early period. The consistently positive effect of cadre status here may, however, result from time variation in the criteria used to select cadres, which have varied appreciably over time. We include having a military occupation (being a soldier) in this analysis because joining the army is widely believed to facilitate upward mobility by improving chances of joining the Party (Xiao 1989). Indeed, the effect of being a soldier on the rate of joining the Party is very large and statistically significant during the Cultural Revolution. It is positive but not very large during the early period, and it is large but insignificant in the recent reform era. Very few individuals in our data were soldiers in any period so the statistical power of this test is low. The impact of being a soldier must be very large to achieve statistical significance when the number of cases in the category is small.

Education also shows some time-varying effects. Before the Cultural Revolution, a junior high school education (the reference category) is associated with the highest rate of joining the party; differences based on education are not statistically significant, however. The pattern during the Cultural Revolution is similar, except that those having college education had the lowest rate of joining the Party ($p < .10$). These patterns are consistent with policies in the Party at that time, which emphasized political loyalty more than competence. In the post-Mao era, the situation reverses: College graduates have a significantly ($p < .01$) higher rate of joining the Party than those with a junior high education (and presumably the other educational levels, too, since they have even lower rates of joining the Party than those with a junior high school education). Clearly, human capital has different political implications in China in different historical periods.

Family background does not have a statistically significant effect on joining the Party. This result may be the consequence of prior selection into an occupation and organization based on family background.

Clearly, as far as joining the Communist Party is concerned, the effects of structural locations depend on state policies at a particular time. It would be misleading to discuss the effects of structural position without considering the particular historical context. Given our limited sample size, we are unable to represent all policy-induced variations. However, our findings are consistent with the general patterns of Party recruitment policies reported in official documents.

SUMMARY

Our findings presented above provide empirical evidence for our arguments about stratification dynamics in China.

Varying Opportunities

Educational and work opportunities are structured by the socialist state, and they are therefore highly sensitive to shifts in state policies and have changed substantially over time since the onset of communist rule in China. Access to a college education, for instance, was severely limited during the Cultural Revolution (1966-79). During this period our data show large-scale movements to low-status occupations, to low-status organizations, and to villages. These declining opportunities were a direct product of radical state policies at that time. But we also observe substantial changes between the 1949-65 and 1980- 93 periods in labor force opportunities and in access to membership in the Communist Party. In light of these findings, the timing of entry into the educational system and into the labor force is clearly a critical factor affecting a person's position in the social structure.

Time-Varying Effects of Human and Political Capital

We also found support for our argument that effects of human and political capital (i.e., education and family background) on life chances vary over time. In the case of entry into a first occupation, a first organization, and the Communist Party, the magnitude of these effects, and sometimes their direction, vary in different historical periods. During the Cultural Revolution, a cadre family background significantly lowered the rate of entering a government agency and raised the rate of becoming a farmer (and moving to a village); however, in other periods, a cadre family background tends to have small but positive effects on entering a high-status occupation. Education shows analogous time-varying effects, too.

Time-Varying Effects of Structural Position

We argued that the effects of occupational and organizational position also vary over time. Our findings concerning the effects of these positions on the rate of joining the Communist Party give some pertinent evidence. The effects of types of organization on the rate of joining the Party vary across the three historical periods. The effect of a cadre occupation is consistently positive over time, but

this may be because the criteria used to select cadre vary over time. Still, it seems clear that an association between a cadre occupation and membership in the Communist Party becomes thoroughly institutionalized by the onset of the Cultural Revolution.

Since most respondents in our sample did not shift across occupations or organizations after their first entry into the labor force (except for sent-down youth, most of whom returned to urban areas after 1979), we believe that the shifting policy-induced patterns of entry into the labor force, such as those we found, have a lasting effects over individuals' life course.[17]

Discussion: The State and Life Chances

Obviously our findings are highly bounded contextually and they should be, given our emphasis on the importance of historical context and political dynamics associated with twists and turns in state policies. However, our arguments have broader implications for the comparative study of stratification.

Our central argument pertains to the time-varying effects of human, social, and political capital and of structural position on individual life chances. In the Chinese context, such time variation was particularly salient during the Cultural Revolution. An obvious question is: Does this period represent an anomaly — a large random shock to the social system that is highly unlikely to occur again? If this is the case, our findings have limited generalizability.

Although the Cultural Revolution represents an extreme case in China's political history, Chinese macropolitical processes are much more dynamic, dramatic, and unpredictable than portrayed by the simplified historical periods used in our empirical analyses. For instance, the Anti-Rightist Campaign of 1957 purged over 550,000 intellectuals who were rehabilitated only twenty years later. In 1960, the Communist Party sent down over one million cadres to the lower levels — about 15% of the total number of cadres then (Zhao 1987). During the Cultural Revolution, 17% of cadres and 75% of high-level officials were interrogated and purged. Including their family members who also bore the consequences of their downward mobility, it is estimated that a hundred million people suffered during this period (Chen & Liu 1991). Indeed, fluctuating state policies are a regularity of political life in China. Because we focused on such life events as first occupation, first organization, and joining the Communist Party, our analyses have not treated the more prevalent and more subtle forms of policy-induced variations in life chances that happen within a given occupation and organization.

One may be skeptical about the importance that we attribute to political dynamics and think that the patterns we have reported are unique to Communist China. Although we have examined China since 1949, our discussion is motivated by broad differences between market and redistributive economies and by the political dynamics intrinsic to state socialism. Political dynamics affect individual life chances in the ways that we have discussed only when politics are closely linked with everyday life. We think that our arguments have implications for all societies where political authority attempts to manipulate individual life chances directly. The processes of resource transfers may take

different forms, depending on the specific institutional structure of political authority, but the effects of political dynamics on individual life chances are — we believe — inevitable in such societies.

Attention to stratification dynamics raises both theoretical and methodological issues in the comparative study of stratification. Theories not only need to give attention to structural conditions but also take seriously evolving political processes, especially shifts in state policies and other noteworthy political events. Our analyses suggest that, to understand stratification in urban China in particular and in state socialist societies in general, one should pay attention not only to the unique institutional structure of redistributive economies, but more importantly to macropolitical processes and state policy shifts. Stressing individual-level resources (social origins, human capital) and lateral group competition, as is common for industrialized market societies, is problematic: Individuals do make choices, and resources do facilitate upward mobility. But the extent to which choices are available and the value of various resources cannot be understood without an adequate knowledge of the macropolitical environment.

We distinguish sharply between stratification processes that follow a political logic and those governed largely by a market logic. The emergence of a central state and political mechanisms of stratification, which is characteristic of (but not exclusive to) state socialist societies, inevitably links state policies with drastic social dislocations. The rise of the welfare state has also enhanced the active role of political authority in stratification processes in industrialized market societies. Governmental social policies in the U.S. have, for example, played a significant role in equalizing opportunities. According to DiPrete and Grusky (1990): "The most important 'independent forces' in advanced industrial systems may be the political policies and programs undertaken by the state itself" (109). As the modern state expands and penetrates civil life, we expect channels of resource transfer to be altered and the effects of state policies on individual life chances to increase. Given the growing role of the state in the labor markets of industrialized market societies, the Chinese experience has implications far beyond China and other state socialist societies.

Notes

1. Whether one should stress the "family resemblance" of all such regimes or the nation-specific departures from a common regime is the subject of much debate. but viewed broadly, the family resemblance is more apparent than national uniqueness.

2. A growing literature emphasizes organizational context and the state in stratification in industrialized market societies, too. See, for example, Althauser and Kalleberg (1981) and Baron and Bielby (1980) on the impact of organizational context and Mayer and Schoepflin (1989) and DiPrete and Grusky (1990) on the role of the state.

3. Potential sample selection bias is another issue. We drew our sample from households that fell in our sampling frame in the two cities. Since our study focuses on urban China, the exclusion of rural areas does not impede our analyses. Random flows of urban residents across urban areas should not cause sample selection bias. One potential problem is the exclusion of those who left the urban areas before our data collection began. For instance, some "sent down" youth remain on farms even today. To the best of our knowledge, however, the

percentage who did not return to urban areas after the send-down policy was reversed is very low (Deng 1993:351) and therefore should not appreciably affect our analyses.

4. A few other types of organizations, such as private firms, exist in some historical periods but occur too infrequently in our data to be distinguished in our analyses.

5. The main exception occurs when a parent holds a "cadre" position after 1949, which takes precedence over class position of parents and grandparents before 1949.

6. In these data, the number of events in any given historical period is too small to have a reasonable level of statistical power if more and narrower historical periods are used. However, at the suggestion of one reviewer, we explored five somewhat narrower periods in our analysis of entry into the Communist Party. The general pattern of results was similar to that obtained with the three broad historical periods. For consistency, we report below only results for the three broad historical periods.

7. A better picture of educational opportunities would be given by the number enrolled in a given educational level divided by the number of graduates from the level below. But we found data only on the annual number of graduates at each educational level. Therefore, Figure 1 only indirectly indicates time variation in educational opportunities.

8. Being a farmer is almost perfectly correlated with a village type of organization.

9. The term *population at risk* or *risk set* refers to the set of individuals who can experience some event. In general, the members of the risk set vary over time. For example, at any given time, only non-Party members who are at least 18 years old are eligible to join the Communist Party, and only people who are old enough to work but who have not yet started to work are at risk of entering a first occupation and first organization.

10. This test treats farmers as censored because so few people enter this occupation except during the Cultural Revolution. Hence, including farmers would give a significant difference over time, even if nothing else changed. The test reported here is more conservative because it pertains to changes over time in effects of covariates on entering only the cadre, professional, and worker occupations.

11. We do not comment on effects of the control variables (gender, place, and age) except when they seem to be of particular interest.

12. The number of people at risk of entering the labor force is 195 in 1980-93 but over 500 in the other two periods (see Table 2). The relatively small number in 1980-93 reflects the fact that individuals younger than 25 were not interviewed. This interviewing rule causes the average age and educational levels of those at risk of entering the labor force to be somewhat higher in 1980-93 than would be the case if a lower minimum age had been used to select the sample.

13. We did not include Communist Party membership in the model because we are examining entry into the first occupation and first organization, and labor force entry usually occurs before a person joins the Party.

14. We treat a move to a village organization as censored in this test (as we treated a move to a farmer occupation as censored in the corresponding test in Table 3) to avoid finding a significant effect solely because moves to a village organization occurred almost only during the Cultural Revolution.

15. We treated entry into the private sector as censored in our analyses because the number of events was too small to perform any multivariate analysis of moving to this destination.

16. We note that relatively similar percentages of Party members were found in Tianjin in the 1980s (Lin & Bian 1991; Walder 1995).

17. We plan to examine these effects in future studies. For a preliminary report, see Zhou, Moen & Tuma 1994.

Decomposing the Intellectuals' Class Power: Conversion of Cultural Capital to Income, Hungary, 1986*

JÓZSEF BÖRÖCZ, *Rutgers University*
CALEB SOUTHWORTH, *University of California, Los Angeles*

Abstract

Konrád and Szelényi posed a powerful critique of state socialism with their formulation of the new class theory suggesting that intellectuals were "on the road to class power." Using a Weberian reading of Bourdieu, we specify empirically one aspect of that critique and examine the statistical effects of cultural capital on income inequalities in Hungary, 1986. While confirming the independent effects of both "education" and "habitus" — potential and realized components of cultural capital — our analysis suggests that certification obtained through formal education is the strongest cultural capital predictor of incomes.

During the years between the end of World War II and 1989, the socialist states of Soviet-controlled Europe claimed to have reorganized society to exclude private ownership of the major means of production. While the political-economic verity of that claim may have been questionable, there was a certain sociological validity to it. Following the Soviet pattern, all socialist states abolished the propertied bourgeoisie both as locus of accumulation and as a socially recognized group.

** Data for this study come from the archives at TÁRKI, the Budapest-based Association for Social Research and Informatics, and were obtained free of charge due to the senior author's affiliation with one of TÁRKI's member institutions. The preparation of this study was supported by grants received from the Center for German and European Studies at the University of California, Berkeley, from OTKA (the National Science Research Fund of Hungary under number T6739), and by further support from the Institute for Political Science of the Hungarian Academy of Science and the University of California at Irvine. Computing facilities were partly provided by the University of California at Irvine. The authors owe special thanks to Ildikó Merkl for providing invaluable help in obtaining the data and Gábor Körösi for some useful initial statistical discussion. We are grateful for detailed comments received from Judit Bodnár, Éva Fodor, David A. Smith, Judith Stepan-Norris, and Max Stevens, and the two anonymous reviewers at Social Forces on earlier drafts. The usual disclaimers concerning the text's remaining weaknesses apply.* *Direct all correspondence to József Böröcz, Department of Sociology, Rutgers University, New Brunswick, NJ 08903-5072 or e-mail:jborocz@rci.rutgers.edu.*

The idea that the abolition of the propertied bourgeoisie did not result in the elimination of the class nature of such societies has been the centerpiece of a powerful critique of state socialist practices (Djilas [1957] 1962b; Gouldner 1979; Konrád & Szelényi [1974] 1979). In its most mature form, the "new class" thesis can be reformulated for our purposes as arguing that cultural capital — possession of which is a marker of intellectuals — replaced economic property as the fundamental structure of social inequality under state socialism.

This article attempts an empirical specification of the new class thesis with respect to income inequalities using survey data from three years before the collapse of state socialism in Hungary. The models presented here sort out the effects of cultural capital and traditional stratification variables on income variation; then the effects of cultural capital are decomposed. The article demonstrates the application of cultural capital to a socialist society and the particular use of the components of cultural capital in a social stratification model of income.

Intellectuals, Cultural Capital, and State Socialism

In the official rhetoric of state socialism, inherited social inequalities were reduced through the redistributive system which allocated resources for private as well as public consumption. The elimination of the social position of the exploiter class, and the ceaseless redistributive action of the socialist state, were supposed to have equalized the relations of distribution. Work on comparative social inequality indicates that during the decades of state socialism levels of social inequality were indeed reduced in comparison to prewar conditions. However, the existence of social disparities and, specifically, income inequalities, cannot be denied.[1] This was especially so toward the late period of state socialism, and particularly in Hungary, one of the state socialist societies that drifted farthest away from the Soviet pattern.

The possibility of intellectuals taking power in a socialist society is not a new idea. Even before the Russian Revolution, Polish-born Bolshevik Jan Machajski argued that socialism was the intelligentsia's aspiration to abolish capitalism and nationalize the means of production in its own interest (Stites 1989). After that revolution, Leon Trotsky ([1933] 1972) attacked what he saw as a "deformed workers' state" and rule by a corrupt bureaucracy instead of the working class. With almost four decades of Soviet and ten years of Yugoslav experience behind him, Milovan Djilas refined Trotsky's criticisms into a theory of "the new class" in which he argued that the ruling bureaucracy had taken on a class character (Djilas [1957] 1962b, 1962a) on the basis of their organizational power: "The bureaucrats in a non-Communist state are officials in modern capitalist economy, while the Communists are something different and new: a new class" (Djilas [1957] 1962b:44).

Finally, in the post-Sputnik Brezhnev years — when groups of humanistic and technocratic intellectuals began to enter the party and government with hopes of rationalizing the state — Konrád and Szelényi developed the idea of the "new class" into a theory of intellectual class interest articulated through a state-run system of rewards for education and technical skill (Konrád & Szelényi

[1974] 1979; Szelényi 1982, 1986-87; see also Gouldner 1979). They argued that increased reliance on experts, combined with the meritocratic educational and political system, provided an environment in which intellectuals gradually came to control the redistributive apparatus of the state, a power that gave them the possibility of disposal in their own interest (Szelényi 1986-87).

An analytical distinction between the propertied bourgeoisie and the cultural bourgeoisie helps explain the evolution of the intellectuals' dominance. In a recent paper, Konrád and Szelényi address a historical characteristic of the belated, semiperipheral development of capitalism in East Central Europe[2] and distinguish between two German terms, *Besitzbürgertum* and *Bildungsbürgertum*, as follows: "we will use the distinction between *Bildungsbürgertum* (the educated middle class, which is bourgeois, or *bürgerlich*, primarily in terms of its habitus, lifestyles, consciousness, or commitment to pluralistic democratic institutions and civil liberties) and *Besitzbürgertum* (the propertied) as a characteristically central European distinction that presumes the openendedness or undetermined nature of the dialectical relationship between these two phenomena" (359). In central Europe, these two aspects of west European bourgeois development were divorced from each other in terms of both space and time, and were located in social groups and behavioral patterns that were distinct in terms of their sociocultural roots, claims of legitimacy, patterns of social networks, and relationships vis-à-vis the state and the world economy. Hence, a key consequence of the transition to state socialism was that the removal of the *Besitzbürgertum* elevated the *Bildungsbürger* practice and its practitioners (some of whom are now called intellectuals) to new heights of social power, prestige, and privilege.

Our analysis is *not* a direct test of Konrád and Szelényi's proposition pertaining to the class nature of state socialism or of the question of whether or not the intellectuals constitute a class. Instead we ask: *If* state socialism is a class society, and *if* the intellectuals occupy a systematically advantageous position in it, then what specific components of cultural capital have positive statistical impact on one specific form of inequality, income levels?

This article first builds a basic stratification model of income. Then it shows the effects of cultural capital on earnings differences under state socialism. Our model uses Bourdieu's (1984) definition of *cultural capital* as "the disposal of taste" or consumption of specific cultural forms that mark people as members of specific classes (1984).

In the north American version of the Weberian tradition, "'status' (*ständische Lage*) shall mean an effective claim to social esteem in terms of positive or negative privileges" (Weber [1920] 1978:305).[3] The components of status are (1) style of life,[4] (2) formal education, and (3) hereditary or occupational prestige (305-6). Cultural capital is Bourdieu's reinterpretation of Weber's theory of status groups. Bourdieu defines *cultural capital* as competence in a society's high-status culture. He argues that it can be broken down into a realized, or *habitus*, and a potential, or *education*, component.[5] The former includes perceptions, appreciation, and specific actions (Bourdieu 1977). Thus, habitus — Bourdieu's conceptually more restrictive equivalent of the "style of life" component of status in Weber — is defined as "a system of lasting, transposable dispositions which, integrating past experiences, functions at every moment as

a matrix of perceptions, appreciations and actions and makes possible the achievement of infinitely diversified tasks, thanks to analogical transfers of schemes permitting the solution of similarly shaped problems" (82-83).

Bourdieu describes education as potential cultural capital because a large part of sociocultural practices are organized by the "dormant" aspects or predispositions contained in individuals' cultural endowments. Denoting not only formal institutional, but also informal aspects of such dormant predispositions, Bourdieu's *education* is a conceptually larger version of Weber's *formal education* (Bourdieu 1986:243-46).

Our analysis follows Bourdieu in operationalizing cultural capital as competence in high-status culture where "high-status culture" is not a measure of specific content, but rather the specific value society places on a given artist, form of expression, knowledge or communication, commodity, or pattern of behavior. We break it down along the two axial dimensions — education and habitus.

Lamont and Lareau (1988) define cultural capital as "institutionalized, i.e., widely shared, high status cultural signals . . . used for social and cultural exclusion" (156). Read from the angle of state socialist class analysis, it becomes clear that Lamont and Lareau need to cast cultural capital as a set of "signals" because they address capitalist society where both cultural capital and economic capital display full and relatively distinct hierarchies of inequality that are not simply reducible to each other. At a minimum, a process of mediation, symbolization, or, as in Lamont and Lareau, "signalling," is necessary between social structures emerging from economic capital and structures of cultural capital.

With the establishment of state socialism, however, private individuals were removed from positions in which they could benefit from exploitation based on economic capital.[6] This empties the property-based dimension of class conflict and opens up new areas as potential dimensions of class formation. While the previous ruling classes could be economically expropriated, their cultural and social practices and tastes could largely endure. With the state as the owner of large-scale capital and the controller of the labor process, formal mechanisms of redistribution lead to the large-scale transformation of the class structure. The hierarchy of the state bureaucracy becomes the basic structure of state socialist society. The internal logic of state organization provides new opportunities for a select group of individuals to use their structural advantages in terms of cultural capital through institutional mechanisms.[7] Instead of being abolished, social exclusion is reorganized and systematized along different lines. Our study examines one particular aspect of this reorganization of exclusion: the conversion of cultural capital into personal earnings.

Our image of the causal mechanism connecting cultural capital and income levels can be summarized as follows: Cultural capital comes in two major forms, education and habitus. Habitus is associated with practices of cultural production and consumption that enable its practitioners to maintain a more detailed, informed, and complex vision of their social world. It is also a source of social respect and prestige. Individuals who are in command of those are better prepared to foresee changes in their environment and have more precise models of the social world available for them. The patterns of taste, judgment, and

distinction that emerge in this process function as cultural reinforcement mechanisms solidifying systematic inclusion and exclusion.

Education is a central marker in this hierarchy. Along with all the advantages of prestige associated with habitus, education confers a further level of advantage in the sense that state enterprises require certain job-specific levels of skills and qualifications to regulate entry and promotion. Furthermore, potential aspects of cultural capital are more fluid, less objectified, and less restricted by existing social patterns of behavior than habitus. Consequently, they are more amenable to complex strategies of advancement in the hierarchical division of labor of this state socialist society. Both habitus and education are expected to contribute to improving the individual's position in the system of distributional advantages, but the effects of education are expected to be stronger and more direct.

Data, Variables and Method

The data come from TÁRKI-III, a general social survey of Hungary executed as a cooperative effort by the Sociology Institute of the Eötvös Loránd University, the Mass Communication Research Center and the Association for Social Research and Informatics in 1986. It uses a three-step stratified sample ($n = 2{,}963$) of the country's adult civilian population.[8]

Table 1 includes the variables, brief descriptions, value labels, means, and standard deviations. The dependent variable of the analysis is the logarithm[9] of the total of all the respondent's self-reported individual incomes expressed in monthly figures in Hungarian Forints.[10] It includes money incomes from work (wages and salaries), social incomes in cash (maternity, retirement or disability benefits, workers' compensation, sick pay, scholarships and fellowships, and aid in cash), and estimates of incomes in cash and in kind from the second economy; for example, second jobs, overtime pay, tips, moonlighting incomes, and revenues from "around the house" farming. However, the income variable excludes social incomes in kind, such as health care, child care, education, housing, and transportation subsidies. While there is an important literature that assesses other sources of inequality under socialism, particularly housing, we see those sources as a separate empirical problem.[11] Our effort is to show that cultural capital matters to income inequality, not that it is the only dimension of social stratification in Hungary. The survey's mean monthly income figure — HUF 6,357.82 per month — is the equivalent of U.S.$138.73 at the annual average official exchange rate for 1986 (KSH 1991), and is almost exactly the same as the estimated national figure of HUF 6,310.80 (U.S.$137.70) provided by the Central Statistical Office for 1986 (KSH 1991). We exclude those cases with no income from our analysis because we have no reason to believe that our model of income determinants would predict zero income. We now detail the baseline measures used to control for income variation and their expected effects and next turn to the cultural capital variables.

Party membership should be a significant contributor to income inequality as advancement to the higher ranks of the occupational hierarchy required party membership. It is coded in two dummy variables: *high party* for those with a

TABLE 1: Description, Value Labels, Means, and Standard Deviations of Dependent and Independent Variables

Variable	Description	Values	Mean	S.D.
Income	Total individual income from all sources (in Forints)		6,357.82	5,057.92
Log income	Logarithm of total income		3.723	.254
High party	Party member with workplace function or higher	0=no, 1=yes	.051	.220
Low party	Party member with less than workplace function	0=no, 1=yes	.091	.287
Age	Age		45.147	16.159
Both sectors	Respondent works in state and nonstate sectors	0=no, 1=yes	.141	.348
Nonstate	Respondent works in nonstate sector only	0=no, 1=yes	.027	.161
Gender	Gender	0=male, 1=female	.525	.499
Work	Respondent actively works for income	0=no, 1=yes	.696	.460
Budapest	Respondent lives in Budapest	0=no, 1=yes	.210	.408
Other city	Respondent lives in other large city	0=no, 1=yes	.348	.486
Basic education	Schooling: complete elementary	0=no, 1=yes	.649	.477
High school	Schooling: completed high-school	0=no, 1=yes	.239	.462
College	Schooling: completed college	0=no, 1=yes	.059	.236
University	Schooling: university diploma	0=no, 1=yes	.049	.216
Number of books	How many books do you have?		310.7	646.7
Read books	How often do you read books?	1=never, 2=sometimes, 3=often	2.174	0.733
Theater	Visits/year to the theater during last year		1.574	3.648
Classical music	Visits/year to classical concert during last year		.390	2.238
Foreign language	Can you speak a foreign language?	1=no, 2=so-so, 3=fluent	1.373	0.686
Trips abroad	How many times have you been abroad?	0-99 or more	4.756	9.520

cell-level function in the workplace, a county-level function, or who served on the central committee; *low party* for simple members. Nonmembership is the implicit point of comparison.

Variables *age* and *gender* are markers of basic socially ascribed traits of the individual. Income should go up as the person becomes older and more capable and down after retirement age. The nonlinear effect of retirement is filtered out by the use of the control variable *work* which marks active labor force participation.[12] Further, gender stratification and systematic gender-based discrimination against women exists in all societies, including state socialist ones.

We use two dichotomous variables to show the respondent's presence in either the *second economy only* or both the first and second economy (*both economies*). The reference category is the majority of the population who participate in the state sector only. Of those who report incomes in our sample, 82.1% are employed only in the state sector, 15.3% are bisectoral, and a mere 2.6% earn incomes solely in the private sector. Participating in the first and second economy are those individuals who draw incomes from the state sector, and who *also* are self-employed, earn tips, conduct farming around the house, receive "gratitude monies" (typically given to doctors), or subcontract from the state. Participating in the second economy exclusively are the small number of respondents who hold no state employment or entitlement; these people are concentrated in agriculture and artisanal self-employment (Böröcz 1993; Róna-Tas 1990).

Finally, two more dummy variables control for the urban/rural contrast and urban primacy: *Budapest* indicates those who live in the capital city and *other city* shows those who live in other settlements officially classified under Hungarian administrative rules as urban.[13] These screen out the effects of cultural opportunities and income earning strategies that exist only in larger metropolitan areas.

Cultural capital is measured via variables organized along the two axes defined by Bourdieu. Formal educational credentials, proficiency in foreign languages, and the number of books the respondent owns measure the education dimension. A series of dummy variables captures different levels of schooling completed, reproducing the emic structure of schooling levels in Hungary, and ranges from complete elementary school education (*basic education*), complete high school (*high school,*) and a college degree (*college*) to a university diploma (*university*). Less than a completed elementary school education is the reference category. The approximate self-reported number of books owned is *number of books*. The ability to speak a foreign language is coded as a three-level, rank-order variable (*foreign language*).

Measures classified under habitus include the number of hours per week spent reading (*read books*); the number of times per year the respondent goes to the theater (*theater*); the number of times per year the respondent attends a classical music concert (*classical music*); and the total number of trips taken abroad during the respondent's life (*trips abroad*).

Measures of certification are expected to be the most fundamental predictor variables in this model. We think certification affects income independently in that most occupations explicitly require specific levels of certification. Parental income/wealth exert some influence on certification, because money can buy

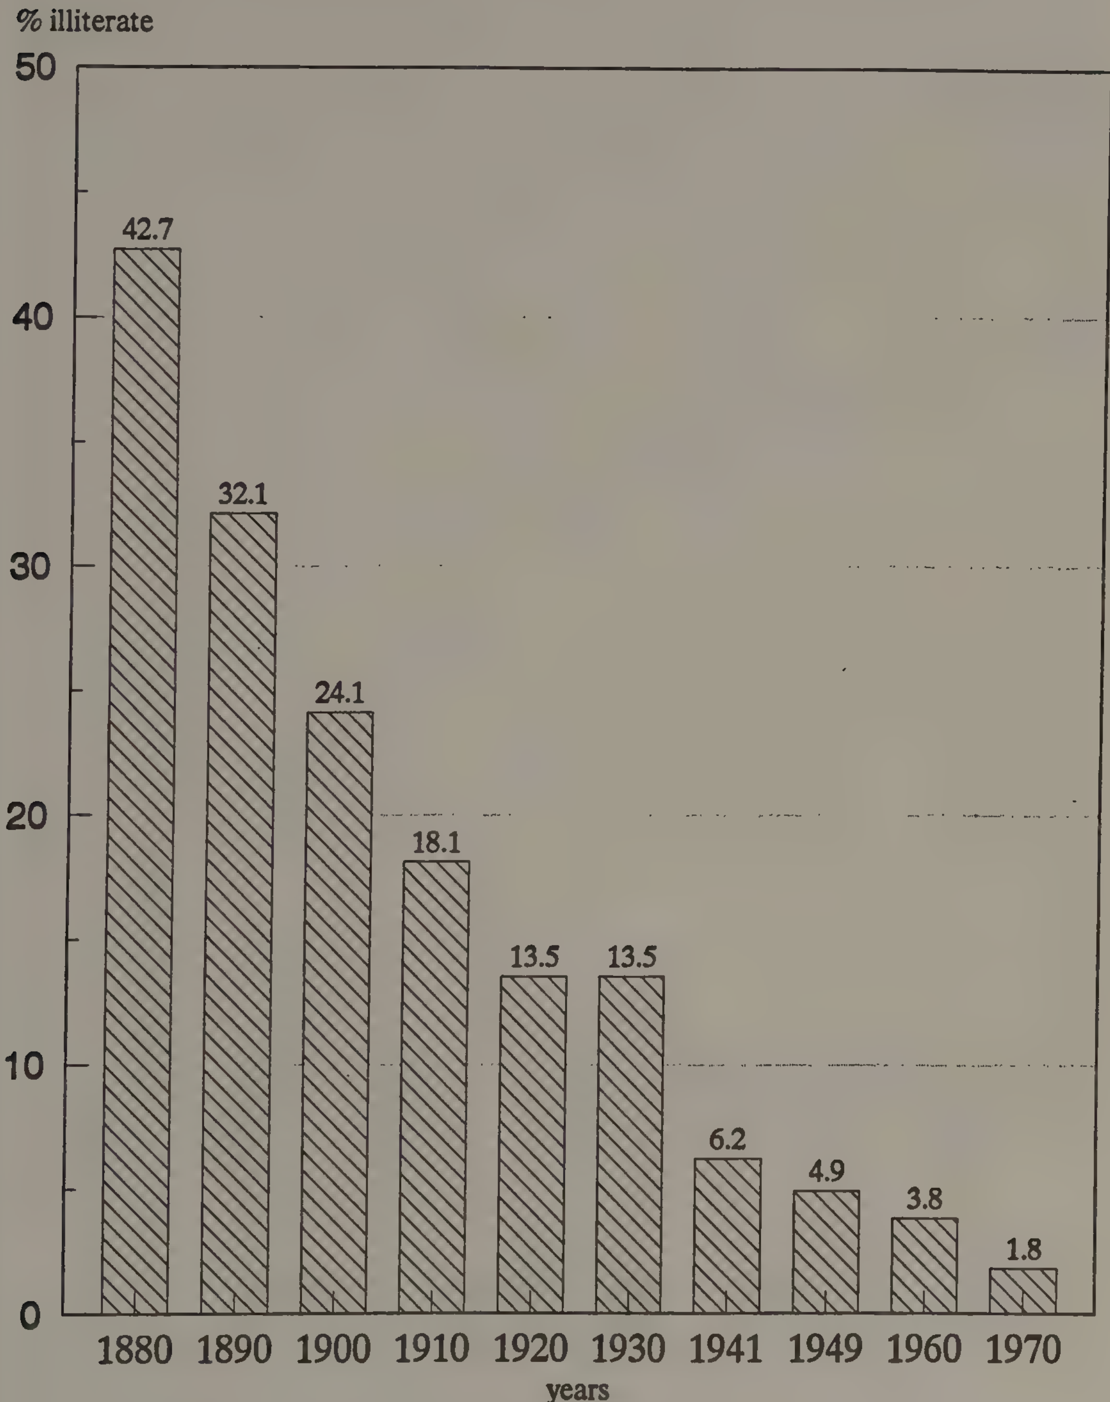
resources that make education easier, but this influence, of course, is much smaller in Hungary than the U.S. where ability to pay is a condition for many educational advancement decisions. In Hungary, educational attainment reflected in certification involves both the drive for economic ends and a particular underlying value system. Individuals' passage through hierarchically structured institutional forms of education exposes them to ideas and endows them with symbolic markers of social prestige and power. Drawing on history, art, and the humanities allows them to envision more possibilities than their immediate, current reality. Success in educational attainment, measured in certification is, for these reasons, likely to be the strongest common trait amongst intellectuals.

While illiteracy rates (summarized in Figure 1) had dropped to below 5% before the end of World War II (Andorka & Harcsa 1990c), it was clearly the advent of state socialism that marked spectacular increases in formal educational attainment among Hungarians. As we summarize in Figure 2, the high school completion rate was hovering around the 5% mark until the late 1940s, to pick up steeply and rise to the level of 22.3% by 1980 (Andorka & Harcsa 1990c). College or university completion rates establish a very similar pattern: They increased from a three-decade constant of 1.3% until 1949 to 4.9% in 1980 (Andorka & Harcsa 1990c).

We consider the number of books an individual owns to measure physical possession of a cultural commodity. If books are acquired through inheritance, then a double dose of Bourdieu-esque "disposition of the past" is present — some bit of family wealth in a cultural commodity form, some active perception — that is, the choice to keep the books rather than unload them for cash. We could argue that the model depicts something else — income — and that an individual might become wealthy and then buy books. While this might initially appear to be a causal ordering problem, the choice of what to buy remains a disposition of taste, an effect of cultural capital. Individuals can spend money in a number of ways, so if the choice is a cultural commodity, especially of the "low-tech" variety represented by books, skeptics still must explain this type of consumption. Buying and owning books still falls into that category of status which Weber labeled "style of life." Cultural capital strongly influences this process; parental wealth/income only weakly. Current income is only a force offering some new set of chances to put cultural capital into action. To the extent that the number of books is an inherited pattern — both in the sense of inheriting the volumes and a specific system — the number of books an individual owns can be considered a marker of the *Bildungsbürger* ethos.

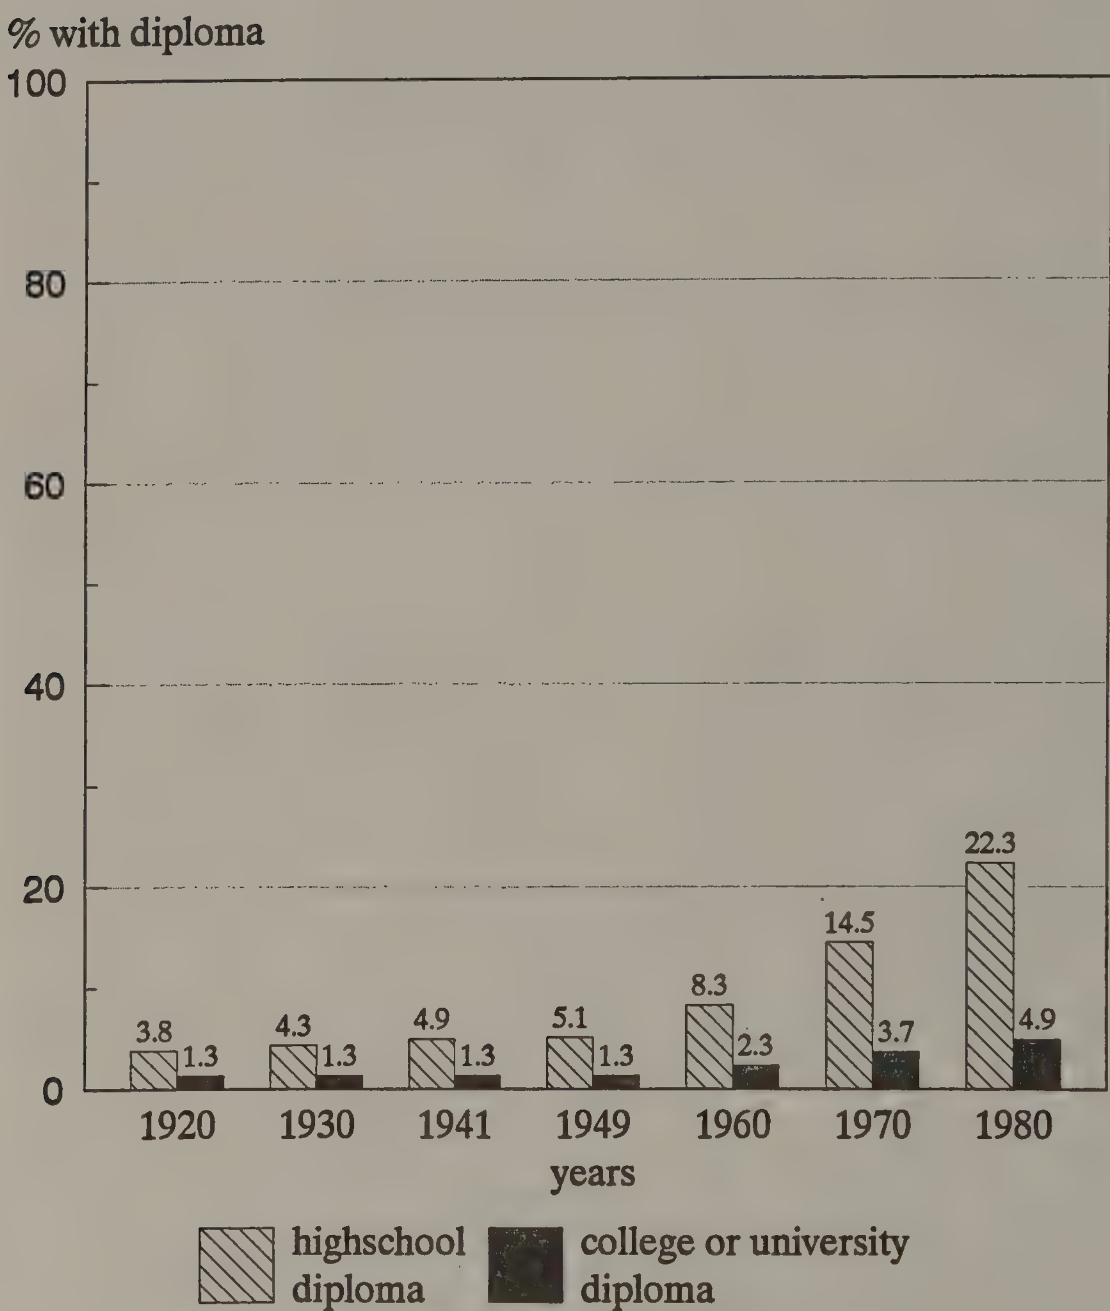
Number of books is distinct from certification in that it does not appear to have the same direct, intentional effect on income — i.e., it is difficult to envision a short-term individual class-mobility strategy based on the act of buying books — and that it offers a specific possibility for the functioning of inherited cultural commodities. A relatively greater number of books can be, however, an integral part of a long-term personal strategy of intellectual "catching-up": Individuals who came from relatively disadvantaged backgrounds, and who engaged in upward mobility on the educational ladder, sometimes increased their spending on cultural commodities. This was especially possible under the state socialist system of cultural subsidies that

FIGURE 1: Illiteracy Rates, Hungary, 1880-1970[a]



[a] Source: Andorka et al. 1990

FIGURE 2: Percentage of Population with Secondary and/or Tertiary Education, Hungary, 1920-1980[a]



[a] Source: Andorka et al. 1990

made book purchases very accessible. The number of books published in Hungary increased from 2,438 in the last prewar year to around 8,000 per year by the 1980s (KSH 1991:19). With illiteracy rates reduced by the time of the onset of state socialism, and spectacular increases in the total output of book publishing houses (Figure 3) rising from 9.2 million volumes in 1938 to 113.1 million in 1990 (KSH 1991:19), Hungary can be considered a highly developed and widely accessible book market by the time of the survey. Such catching-up strategies suggest the possibility of the workings of an acquired *Bildungsbürger* pattern among the *nouveaux intellectuels* taking advantage of the socialist state's efforts in increasing cultural capital among the population in general.

Because proficiency in foreign languages comes in large part from a combination of schooling, parental input, and travel experience abroad, language ability is a gauge of the educational component of cultural capital. It also measures education independent of formal institutional recognition. Bi- or multilingual parents are, of course, in a strong position to establish this skill as heritable education, just as wealthy or well-connected parents can provide opportunities of travel. Growing up abroad — as is the case with children of elite intellectuals, foreign traders, and members of the diplomatic service — virtually guarantees advantages in this area. Foreign language proficiency, however, is not necessarily connected to educational attainment or privileged background: Members of Hungary's ethnic minorities, ethnic Magyars who grew up in the neighboring countries as ethnic minorities there and subsequently immigrated to Hungary, documented and undocumented former guest workers abroad (with experience ranging from East Germany, the Soviet Union or Libya to West Germany and other west European countries), along with a small number of foreigners who married Hungarians and settled in Hungary — all these people are found in the group marked by high levels of foreign language proficiency.[14]

Book reading is a gauge of the behavioral component of habitus. We can assume that this measure is largely independent of income or parental income as free libraries and book lending between individuals allow people to read regardless of whether they own the books. Public libraries that were practically free showed impressive growth during the four decades of state socialism in Hungary. As Figure 3 shows, their total holdings grew almost 23 times between 1950 and 1990 (KSH 1991:19). If one appreciated reading, it was certainly there for the taking, especially in the urban setting.

Theater and classical music measure yet different pieces of the habitus in cultural capital. These are markers of direct cultural consumption without producing tangible and displayable commodities. Perhaps they reflect some weak external influence from income in that those who can afford tickets without hardship may attend performances more often. But here again, the choice of attending artistic performances over other alternatives is the important moment. State subsidies also reinforce the accessibility of these cultural commodities. Before the collapse of the socialist system of cultural management, all Hungarian public cultural institutions, such as theaters and concert halls, received substantial state subsidies, some exceeding the equivalent of several times their ticket revenue. In 1987, for instance, the 41 Hungarian full-time professional theaters gave 13,082 performances (KSH 1991:289) so that they saw

FIGURE 3: Annual Volume of Books Published (1938-90) and Library Holdings (1950-90), Hungary (millions)[a]

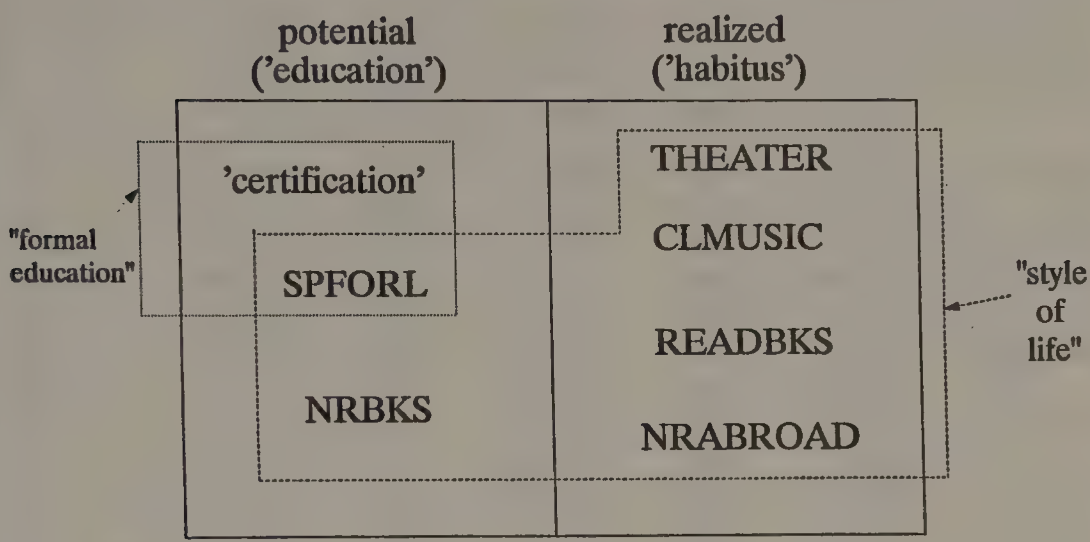
FIGURE 4: Conceptual Model and Variables of Cultural Capital



an average of 56 theater visits for every 100 members of the population (Andorka & Harcsa 1990b:211-12).[15] Attendance at classical music concerts grew from 2 to 10 per 100 population between 1960 and 1990 (Andorka & Harcsa 1990b:211-12). The mean ticket price for professional live theater performances was HUF 59.70 — the equivalent of U.S.$1.27 — in 1987 (KSH 1991), less than one percent of the average net monthly income recorded in official statistics.[16] State expenditures on "collective consumption in kind" can be seen as cultural subsidies to both the process of artistic production and the consumer — the latter being an instance of the positive feedback effect between intellectualness and access to redistributive advantages from the state.

Travel is yet another variable in the nexus between income and cultural capital Weber called "style of life." Without habitus and income, individuals will not travel, but, as with books, classical music, or theater, travel cannot be understood as simply a function of income. Travel is a reproduced behavior and something that one's parentage undoubtedly helps individuals appreciate, decode, and consume. This measure may also suggest an undrawn link between occupational prestige and travel as an element in status: Travel could be part of the prestige of some job that might, in turn, be seen to feed income.[17]

This question emerges here: Does this amalgam of measures adequately capture "intellectualness"? Specifically, how does this particular set of measures of cultural capital add explanatory power to a model beyond the basic stratification variables in the context of Hungary in 1986? Decomposing cultural capital into these variables allows analysis impossible at higher levels of abstraction. Many studies of cultural capital treat cultural consumption without a theoretical justification for what is consumed (Nan Dirk DeGraaf 1988; P. DeGraaf 1991;

Ganzeboom, DeGraaf & Robert 1990; Katsillis & Rubinson 1990; Robert 1991). In their work on the intergenerational reproduction of cultural capital, Ganzeboom, DeGraaf and Robert (1990), for instance, test variables representing cultural capital without specifying any conceptual relationship among them. Further, their test is not contextualized in terms of any class or group receiving the benefits of the resulting stratification. The Konrád-Szelényi thesis allows us to see beyond the mere existence of some source of inequality and places the results in relation to the socioeconomic power structure.

Figure 4 places the variables selected for the analysis in the context of our conceptual model. This set of variables is broken down into Bourdieu's two basic types, education and habitus. We have superimposed Weber's categorization of style of life versus formal education on Bourdieu's framework to show the conceptual overlap between them.

For our purposes, we consider people scoring high on these measures to be exhibiting "intellectualness," but it may be possible to score high on some of the less interrelated variables and not be an intellectual. For example, a retired person could read many books without being adequately characterized by any of the other internal measures of cultural capital; it is one of only a few forms of entertainment open to a less-than-mobile pensioner. But someone scoring high on two or more measures, and especially from both categories, suggests the presence of cultural capital.

The statistical analytical method chosen for this analysis is hierarchical regression analysis. First we establish a baseline model predicting the logarithm of income. Then we test the influence of the individual elements of cultural capital in a series of models of income, examining the significance of the improvement of the model for each of the component variables vis-à-vis the baseline model.

Results

In Table 2, each column is a separate hierarchical model showing the effects of a specific component or concept within cultural capital. The far left column, "baseline," models only the stratification variables upon which the cultural capital models improve. Hierarchical regression models provide a means to test blocks of variables in their conceptual whole against the effects of individual measures of cultural capital.

As Table 2 reveals, all the baseline variables except one are significant ($p < .001$) predictors of income in the context of the baseline model. Net of the effects of withdrawing from the labor force, each year that a respondent grows older (*age*) yields higher incomes.[18] Furthermore, gender effects are pronounced and women's income disadvantage is very resistant to variation throughout all models. The party membership variables both contribute to higher total incomes, with the advantage of *high party* slightly larger than *low party*.

Among the baseline variables that describe work, labor force participation has the largest effect on income. Working in both the state and nonstate sectors proves to be a more effective income-earning strategy than only holding a state-sector job (the reference category). The radical withdrawal from the state sector

into exclusively private sector work was not a path to higher incomes. In 1986, this was a very small group; 79 cases in our sample.[19]

The urban/rural contrast and urban primacy also effect incomes. Those who lived in Budapest attained a 17.8% higher income; those who lived in other large cities, 5.9% when compared to the remainder of the population. These results suggest that there were economic opportunities and higher wages in the urban areas and the capital. Such differences also affect cultural consumption as they coincide with cultural institutions such as theater, ballet, and musical groups that may not be seen in the outlying areas. In all, the baseline model suggests a diversified system of income variation. With 40.38% of the variance in income explained, it provides a strong baseline for the examination of the marginal effects of various components of cultural capital on income.

Next, the marginal effects of each cultural capital variable or set of variables is tested beyond the baseline model. The first set of variables pertaining to certification was hypothesized earlier to be the most important component of education and of cultural capital. The increment explained variance associated with certification — $R^2_{cha} = .0413$ — lends strong support to that expectation.[20] We find a systematic pattern associated with the income effects of each level of certification. Higher levels of certification are associated with higher levels of remuneration. The metric coefficients indicate a monotonically increasing pattern as we move from "incomplete elementary school" to "university diploma." As we move from lower to higher ranks of certification, we can take it with ever greater certainty that the statistical effects of certification on income are not attributable to chance.

Certification eliminates one-third to one-half of the explanatory power of party membership or rank. The fact that no other measure of cultural capital tested in these models deducts from the income-generating statistical effects of party membership and rank to the same degree as certification suggests that those with formal education are drawn into membership and the more active party ranks. The partial overlap between party rank and certification levels is also an implicit empirical measure of the degree to which the merger between the political and the intellectual elites took place in Hungary, as predicted by Konrád and Szelényi ([1974] 1979) over ten years before the time of our survey. These results suggest a *partial* overlap: Although the inclusion of the certification variables reduces the magnitude of party membership and rank, the direction of the effect of the measures of party membership and rank remain the same. This suggests that certification does not simply determine party membership and rank.[21] By the late socialist period, the merger of the party and certification hierarchies remained rather limited.[22]

The certification variables affect party rank unequally such that *high party* contributes slightly less to income than *low party*. In this we see that not only are a significant portion of the benefits of party membership from educational credentials, but that — net of education — it is joining the party, not working to become a high-ranking party official, that increases income the most. This result indicates that the system of rewards advantaged those with a state-sector job (apart from political involvement) *and* a low, often nominal, level of political commitment to the vaguely defined objectives of the ruling party. This combination earned higher incomes than those with a higher-level political

obligation and the responsibility that came with choosing a more exclusively political career.

An additional, conceptually important result pertains to the changes in the strength of the *age* coefficient. In the context of the baseline model *age* is significant ($p < .001$) with a weight of $\beta = .081$; however, when certification is added, the weight of age increases substantially ($\beta = .112$). This indicates that each one-year change in age is associated with a larger increase in income. In substantive terms, the result implies that the expected gradual increases associated with age (having to do with job seniority, experience, etc.) can be observed more within each level of certification: Educational degrees demarcate from each other somewhat separate systems of seniority and experience.

Finally, certification has modest effects on labor force participation and the sector of employment. The decline of the *work* coefficient suggests that more of the educated tend to work. The increase in the *both sectors* coefficient suggests that those working in the state and nonstate sectors have fewer formal educational credentials than those solely within the state sector. This suggests that, by 1986, informal income earning practices had penetrated all segments of the Hungarian society, quite irrespective of educational attainment. Second economy participation was not, then, a unique economic outlet for the intelligentsia.

The geographic variables are substantially reduced with the control for education. This shows the concentration of those with higher education in the urban areas. Again, this reenforces the importance of controlling for settlement type in examining cultural practices associated with intellectuals.

When examined separately from each other, all six of the remaining variables of cultural capital show significant positive effects on income, although the magnitude of their coefficients is more modest than those for certification. In contrast to certification, the inclusion of the remaining measures of cultural capital does not take away from the relative marginal importance of political capital: The coefficients of party membership and rank remain virtually constant throughout the six alternative models. Possession of books, ability to speak a foreign language, book reading, theater and concert attendance, and travel abroad are characteristics and behaviors that are not, by and large, associated with the degree of affiliation with the ruling party.[23] The returns to cultural capital also do not vary by economic sector.

We are not attempting to measure "party culture," although such a phenomenon did exist. The party had special schools, encouraged specific kinds of literary and art expression, arranged its own social retreats and, as in the case of high cadres, was a vehicle for organizing hunting parties and special resorts. There was some overlap between certain elements of party culture and cultural capital (high-status culture) since ruling groups typically adopt some of the practices of their predecessors. However, the efficacy of cultural capital as we use it is in its independence from direct ruling class control; it is a marker, largely produced through educational institutions and the family, that allows people to discern a more complex social reality. Cultural capital is thus not simply the sum total of the patterns of conspicuous consumption by the ruling

class or the genres of artistic expression approved of by the culture and propaganda departments of the Central Committee.

Table 2 (the three columns on the right-hand side) shows the test of the relative magnitude of these measures of cultural capital in the context of their various combinations. The "education" column estimates the combined effects of the three "education" components of Bourdieu's cultural capital — "certification," the number of books and foreign language proficiency — on earnings. The modest independent effects of *number of books* and *foreign language* are overshadowed by the power of certification as the strongest predictor of income: The effect of the number of books is cut by over half. The influence of fluency in a foreign language diminishes completely. In contrast, reductions in magnitude and statistical significance in each of the measures of certification are negligible.

The next column estimates the joint effects of our variables pertaining to the habitus component of cultural capital. Three of the four variables that are significant in the separate models — *read books, theater,* and *trips abroad* — maintain much of their effects. The collective effect of the habitus variables ($R^2_{cha} = .0232$) is noticeably smaller than that of "education" variables ($R^2_{cha} = .0430$), although both are statistically significant ($p < .001$).

The panel at the extreme right-hand side of the table presents our full model of income variation. It suggests that certification is the most important component of our model of cultural capital: All measures of certification preserve their direction and much of their magnitude while greatly reducing the effects of the cultural capital variables. Reading and possessing books and listening to classical music become insignificant in the face of certification and the other cultural controls. *Theater* and *trips abroad* retain a modicum of their explanatory power and ability to distinguish intellectuals net of education, location, and the other controls.

In the context of the full model, the effect of foreign language proficiency becomes negative and statistically significant at the $p < .05$ level. We attribute this change to the following mechanism: The inclusion of a large number of cultural capital variables — including measures for both formal certification and habitus — captures the effects of formal education as well as the *Bildungsbürger* patterns. As a consequence, the remaining effects of proficiency in a foreign language are those that have to do with ethnic minority status or personal background as a former member of the large ethnic Hungarian minorities of the neighboring states.[24] We can discard possible confounding effects between *foreign language* and age, labor force participation and involvement in bisectoral income-earning activities.[25]

That the full model demonstrates an effect for certification and some of the cultural capital variables is a substantial finding. By their very nature, cultural distinctions are more difficult to recognize, quantify, and measure than ascribed characteristics or the locations of home and work.

Discussion and Conclusion

The picture that emerges from this study is one of a material force embodied in the deployment of cultural capital. Rather than an exclusive view of culture as language and shared understanding of ideas, as an art that is to be passively appreciated in quiet separation from those mundane aspects of life that have to do with social action and orientation toward economic goals, in these results we see culture taking on a commodity-like form. The more of it someone has, the more can be converted into systematic distributional advantages or used for the satisfaction of economic ends. Our results can be summarized as follows:

First, the field of cultural capital has a hierarchical internal organization, with the conferral of certification as its focal component. It is mainly through certification that cultural capital was transformed into systematic distributional advantages in the Hungary of the late state socialist period.

Second, levels of certification operate as markers allowing the operation of finer distinctions, such as age, mainly within particular levels of certification.

Third, the strength of the relationship between level of certification and income increases as we pass from the lower to the higher levels of formal education, suggesting that the closure of the ranks of certification increases toward the higher end of the certification scale.

If one accepts, as we initially did, the Konrád-Szelényi thesis concerning the class nature of state socialism with intellectuals as its privileged beneficiaries, then the results presented above indicate the existence of basically two main routes to class mobility under late state socialism: (1) via low-level affiliation with the ruling party and (2) through increasing one's potential cultural capital, specifically, the components that correspond to Weber's "formal education." We have found support for a broader Bourdieu-esque conceptualization of the field of cultural capital in the significance of the single measures of "style of life" and specifically, habitus variables. The statistical models do suggest to us, at the same time, that the coherence of cultural capital is organized by the second Weberian component of status, formal education, as distinct from the style of life.

The implications of this set of findings are two-fold. First, it portrays late state socialism as a credentialing society whose system of basic material rewards can be apprehended through a Weberian-Bourdieu-esque model of formal educational achievement. Second, the demonstrated — more moderate but also somewhat resilient — positive effects of habitus variables suggest that a human capital interpretation of our findings is inadequate unless contending explanations are able to draw an unambiguous causal link between the frequency of such components of habitus as book reading, theater attendance, and travel abroad as individually utility-maximizing income earning strategies.

If it is not cultural capital in general, but a specific set of cultural capital variables that confer distributional advantages to individuals in a state socialist society, then there is reason to argue that the main avenue for the conversion of cultural capital to income leads through labor market processes, specifically through the standardized allocation of segregated job opportunities according to levels of formal education. As the overwhelming majority of employment under late state socialism continued to be in the state sector, our results

reinforce the image of an educational merit-based system of state-allocated inequalities transferred primarily through labor market position.

Our results show that the inequalities of the pre-state-socialist order are in part reproduced and in part reorganized. As the increases in various measures of education and habitus attest, it would be wrong to assume that the rich or the old bourgeoisie possess all the cultural capital via inheritance. Still, despite the greater access to education and culture provided in the Hungary of the 1950s through the 1980s, it would also be mistaken to argue that anyone could wield cultural capital as a mechanism for greater income. Not everyone will know that such a route to privilege exists, nor would they all succeed in the endeavor. Just as the majority in a capitalist society cannot pull on their bootstraps to change their class position, individuals in a state socialist system cannot use cultural capital as a universal access code for economic power.

These findings allow a further speculation concerning a possible interpretation of state socialist practices in cultural capital. If certification is so much more important than all other components of cultural capital as it appears from the above results, then we should expect marked differences in the class effects of cultural subsidies dispensed by the socialist state. An implication of our findings is that the potential impact on class mobility of state spending on the equalization of access to education is much greater than that of all other forms of cultural subsidies. Let us note that, according to Andorka and Harcsa (1990b), a marked drop in state funding for education — implying a serious closure in access to certification — occurred during the 1970s, exactly the period in which Konrád and Szelényi documented the appearance of intellectuals on the road to class power.

Our model can be improved in a number of ways. Time series data would enable researchers to identify the exact dynamics of changes in the conversion of cultural capital to income in Hungary. An inclusion of data for the parents' and grandparents' generation would make it possible to separate more clearly the effects of the *Bildungsbürger* ethos from individual cultural mobility. A replication of at least the most crucial questions of the survey we have analyzed would make it possible to design a before/after study to decipher the effects of social change after state socialism on the processes of conversion. The model could be further specified by seeking out associated variables of intellectualness (such as the effect of access to, and the use of, social networks[27]) and by specifying the labor market route of conversion through some measure of occupational position and institutional power.

Notes

1. Between 1962 and 1987, the ratio of the net volume of officially recorded income in the top and bottom income deciles varied between 3.8 and 5.18, estimated at 4.64 in 1987 (Andorka & Harcsa 1990a:109).

2. The concepts come from German historiography (e.g., Kocka 1981, 1987; Lepsius 1987; Rüschemeyer 1987). Due to the historical lateness of German industrialization, the bourgeoisie was fragmented in part due to its ties to the disparate organs of the German state (Blackbourn 1991). The educated and propertied bourgeoisie occupied separate spheres with different relations to the market, sources of economic security, types of education and recruitment to their respective professions. Arguably, it was this split that prevented the German bourgeoisie

from assuming the unifying role its counterparts had fulfilled before in France and England until World War I (Maier 1975). Zoltán Tóth (1991) offers an erudite application of this conceptual apparatus to Hungarian social history.

3. In this analysis, we have no room to address the obvious ambiguity of the English translation of the Weberian German term *ständische Lage* — "status" vs. "estate" or "rank" (Kozyr-Kowalski 1983; Wenger 1980). As shorthand, we adhere to the usage adopted in stratification studies. This problem is taken up in much more detail elsewhere (Böröcz 1995).

4. We are aware of Abel and Cockerham's (1993) recent warning concerning the mistranslation of Weber's original concept of *Lebensführung* as "style of life" instead of the more exact "life conduct."

5. Christian Joppke (1986) uses the intuitively appealing terms "institutionalized" versus "internalized" cultural capital to denote the distinction between education and habitus. We avoid using this terminology because they are conceptually not orthogonal (i.e., "internalized" cultural capital or, habitus, is no less "institutionalized" than education and *vice versa*).

6. In reality, none of the "socialist" states managed to abolish completely the category of non-state property: A non-collectivized peasantry of various proportions remained, and so did numerous private artisans and other "own-account workers." However, the relative importance of this property form has been minuscule due to serious constraints on the process of capital formation by the "socialist" state, in effect (1) limiting the number of employees to be hired by such establishments (in Hungary, that limit had been 4 until the mid-1980s when it was raised to 15); (2) restricting the availability of capital goods to very small-scale and low-profitability equipment; (3) withholding business credits and systematically encouraging (sometimes even subsidizing) conspicuous final consumption; and (4) the systematic harassment of those successful in being able to accumulate notwithstanding the above measures.

7. Konrád and Szelényi summarize their position on the class reproduction mechanism under state "socialism" this way:

No serious claim can be made about the formation of a class unless the analysis can identify a position from which these agents can exercise class power. In the *Intellectuals on the Road to Class Power*, we believe we identified such a position in the institutions of the redistributive economy. In that book, our argument was that in a statist economy, the redistributor occupies a position that is analogous to that of property owners in a capitalist society (Konrád & Szelényi 1991:352-53).

8. The sample is structured according to settlement type, age group and gender. The data come from three subsamples of 1,000 respondents each (TÁRKI 1988). The sample was managed by Éva Iván. Sociologists Róbert Angelusz, Ágnes Bokor, Tamás Kolosi, and Róbert Tardos were the principal investigators of various parts of the survey. Some results have been presented in Angelusz and Tardos (1991).

9. Logarithmic transformation of total income was used to capture the curvilinear nature of income data. This way, the metric regression coefficient can be interpreted as percent increment in income per unit increase in the predictor variable (Petersen 1989:228).

10. Following notation used in international banking, Hungarian Forints are abbreviated as HUF.

11. Income in no way captures the full range of inequalities in Hungary. This is because, first, a high proportion of income is accessed through collective consumption that is not individually divisible. Second, the fluidity of monetary incomes is much higher than some in-kind assets, namely housing. The correlation between total income and estimated housing value in our sample was .118. It was partly this insight that initiated Konrád and Szelényi's theory.

Despite these limitations, the Hungarian economy in 1986 was the product of numerous reforms which monetized many formerly in-kind transactions with new accounting practices. The central bank even held hard currency reserves approximately equal to the value of Forints saved. Moreover, while Konrád and Szelényi drew their hypothesis from housing inequality, they — and much of the literature emerging after their work — treat their proposition as generalizable.

12. It also controls for absence from the formal labor force for other reasons, e.g., student or homemaker status, persons on maternity leave, etc.

13. The categorization of settlements into "urban" (*város*) vs. "rural" (*nagyközség* or *község*) and the various finer gradations within each of those categories (which we do not use here), was an important manifestation of the manifold classificatory struggles that took place during the last three decades of state socialism in Hungary. It reflects complex considerations pertaining to area and population, infrastructural endowments, administrative function, the size and character of the enterprises, and the intricate issue of the "significance" of all of the above as filtered through the capillaries of the political system.

14. For more on some of these flows, see Böröcz 1992.

15. Theater statistics also reveal sharp geographical inequalities: Theater visits per 1000 population ranged between 1479 in the capital city, Budapest, and as low as 46 and 81 in some of the most rural counties (KSH 1991:287).

16. Theater attendance peaked sometime around the early 1960s with almost 6.5 million visits in this country of 10 million inhabitants. The number of theater visits has been on the decline since then, falling slightly below 5 million by 1990 (KSH 1991:19).

17. Our data allow only a blurry measure of travel abroad: the number of trips. This admittedly confounds the purpose of the trip (business or pleasure), the destination (East Bloc or the West), and distance (neighboring country vs. others). While foreign travel to the West required exit and entry visas and hard currency, by 1986 the majority of administrative travel restrictions had been eased and visas were rarely denied in Hungary. Hard currency was quite widely available through the second economy and, specifically through contact with incoming Western tourism (Böröcz 1996). So while *trips abroad* must be viewed with caution, in the Hungarian context travel is closer to a cultural choice than exclusively the province of state bureaucrats and those with party connections.

18. While the weight of the *age* variable might appear small compared to *work*, for example, the effects of the other variables are built up over the life course and might be more accurately compared to the effects of 10-20 year periods (although that is not our purpose here).

19. The disadvantage associated with being only in the private sector is a strong finding that contradicts much of the existing literature about the dynamism of entrepreneurship and the power of the free-market sector over the state sector. At least in 1986, that logic does not appear to hold; second economy production is rather an important sideline of work, not an alternative. Space does not permit us to explore this further here.

20. In an alternative model not presented here, we represented certification in a single rank-order variable, assuming equal distance among each of its categories. That step also yielded an increment significant at the $p < .001$ level.

21. The low coefficients in the zero-order correlation matrix between party and certification variables (see below) suggest a similar conclusion.

	Basic Education	High School	College	University
High party	-.160	.049	.103	.148
Low party	-.139	.054	.109	.082

22. This conclusion is reinforced by an alternative model in which we tested for the additional effects of an interaction term composed by (1) a dummy variable separating all party members from nonmembers, and (2) one grouping those with tertiary education apart from those less educated: The *F* test of the improvement yielded by the model with the interaction term over our full model was not significant statistically.

While the party and educational hierarchy were not identical, educational credentials were one mechanism the party used to increase its legitimacy. From the late-1960s onward, the party claimed that technical competence, not political loyalty was its first consideration in promotion of industrial managers. During this period, the party also maintained its own schools and special avenues of admission to the more prestigious public universities and institutes (to permit its cadres to attend despite strongly meritocratic admissions policies).

23. The zero-order correlation coefficients between party membership/rank and the remaining measures of cultural capital signal association that is sporadic if not absent:

	Number of Books	Foreign Language	Read Books	Theater	Classical Music	Trips Abroad
High party	.097	.088	.118	.101	.052	.088
Low party	.064	.048	.091	.036	-.004	.090

24. Ethnicity- and immigration-related variables are unfortunately not available in the dataset.

25. The zero-order correlations between these variables are, respectively, -.021, -.012 and -.063.

26. See, e.g., Angelusz and Tardos 1991; Böröcz and Southworth 1995.

Abstract

Facial dominance of West Point cadets, measured from their graduation portraits, is known to be related to cadets' ranks at the military academy, but it has been reported to be unrelated to their ranks in later career (Mazur, Mazur & Keating 1984). With improved methods of data collection and analysis, we show that cadets' facial dominance, while still unrelated to their ranks at midcareer, is related to promotions in late career, 20 or more years after the portraits were taken. These results suggest that the absence of physical features from current models of status attainment is a serious omission.

Influenced by Blau and Duncan (1967), studies of status attainment have focused on family background and education as primary determinants of one's occupational rank. Despite repeated suggestions that a person's physical appearance also has important effects on his or her life chances (Berscheid & Walster 1974; Gillis 1982; Guthrie 1976; Hatfield & Sprecher 1986; Mazur & Robertson 1972; Patzer 1985), physical features of the face and body have been virtually ignored in modern research on status attainment.

Studies relating physical features to personality were popular during the first half of this century (Gowin 1915). Among the best known is the "somatotype" research of Sheldon (1942), whose claimed relationships between body type and temperament were treated skeptically because of biases in his method, though careful replications by others have verified some of the correlations (Child 1950; Cortes & Gatti 1972). Stogdill's (1974) review of numerous early studies, mostly of school-age groups, concludes that leadership (measured in

diverse ways) is correlated with height and with a mesomorphic, or athletic, physique.

It is a common observation that certain individuals have "dominant-looking" faces whereas the faces of others are perceived as submissive. American subjects reliably sort facial portraits along a dominance-submissiveness dimension, and these portraits are given similar ratings in a wide variety of cultures around the world (Keating, Mazur & Segall 1981a, 1981b). Anecdotes suggest that dominant appearance is correlated with actual status attainment, especially within the military, as when Atkinson (1981) refers to the "lantern jaw and chiseled features prized in military officers" or the "square-jawed looks . . . considered vital" in a first captain at the U.S. Military Academy at West Point (1989:118). Also consider this description of a fictitious first captain, written by an academy graduate: "He had one of those young Gregory Peck faces, the dark handsome good looks of a born general. It had always seemed there was an unwritten requirement that first captains and other high-ranking cadets be attractive . . . , not just good-looking, but . . . idols. Statues to the American idea of cadet. . . . At 6'1," 185 pounds, a letter man in soccer and lacrosse, he was the ideal first captain. There was a certain awkwardness — intimidation — in his presence" (Truscott 1978:414).

Mazur, Mazur and Keating (1984) tested these anecdotes, asking if West Point cadets with dominant-looking faces, or who were tall or athletic, were promoted higher than classmates with less impressive looks. Cadets from the class of 1950 were rated as facially dominant or submissive by judges who viewed their graduation portraits. Dominant-looking cadets were indeed promoted to significantly higher ranks than submissive-looking cadets in their junior and senior years at West Point. However the investigators found no relationship between facial dominance and rank attainment over the next 20 years of military service. Athletes enjoyed some advantage in promotion throughout their careers, but height was generally unrelated to rank.

The investigators were puzzled that rank correlated with facial dominance while at West Point but not in later career, and they suggested four plausible explanations.

(1) A cadet's rank is the cause rather than the effect of his appearance in the yearbook portrait. Cadets who enjoy the status of officers communicate their position through erect posture and perhaps through facial gestures, which are recorded in the photograph.

(2) As men enter middle age, physical features lose their earlier relevance for hierarchical placement, at least in comparison with nonphysical features.

(3) Facial features remain important throughout the career, and they continue to influence the promotion board, which requires an updated photograph of each candidate. But a man's face changes over the years, so his appearance in a graduation portrait bears little relationship to his appearance in middle age.

(4) Facial appearance is a leadership quality that matters most in primary groups, when those recommending promotion know the candidate personally. That is the case at West Point where the decision is based on evaluations by cadets and tactical officers, and on promotion to the highest ranks, when the small pool of candidates is again known by those in judgment. At

the junior and middle ranks outside West Point, the candidates are usually unknown to promotion boards and decisions are based on extensive officer evaluation reports, career patterns (whether candidates have had the requisite operational and command positions in the right order and within prescribed time limits), and seniority. Senior officers, however, will all have outstanding evaluation reports with little to distinguish between them. Seniority considerations on this level lose their weight.

Another plausible explanation is sampling bias: West Point graduates make up only 5-10% of all army and air force officers. Also, West Point cadets might be selected more for physical (including facial) appearance than officers who received their commission elsewhere. Thus, while facial appearance may be important for promotions on all hierarchy levels, if we study a sample containing West Point cadets only, this factor may be masked because even cadets with, by West Point standards, average facial appearance, might look more dominant than the majority of junior and middle officers who are not in our sample.

We should then observe a correlation reappear between facial dominance and rank among those men in the sample who obtained promotion to general, since most are from West Point: The percentage of West Point graduates among all brigadier and major generals from World War II until the mid-70s was between 45 and 80%, among all lieutenant and full generals was between 50 and 100% (Moore & Trout 1978); in the early 1980s among all generals it was 40% (Atkinson 1989:496). In our sample, 90% of all promotions to brigadier and 65% of all promotions to major general occurred by 1975, 82% of all promotions to lieutenant and 66% of all promotions to full general occurred by 1980.

Now we are able to evaluate these diverse hypotheses. In 1990, members of the class of 1950 were questioned about their military careers, which by then had all been completed. At the time of the survey, there were still 540 survivors of the original 670 graduates, making the class an ideal object for studying careers in an occupational hierarchy. A refined analysis of these new data provides considerable clarification of the promotion process and some correction of the relationship of facial dominance to military rank attainment.

Careers of the West Point Class of 1950

Like all cadets, the class of 1950 entered the military academy as formally undifferentiated plebes, but in their junior year they were ranked as corporals or privates. In senior year about one-quarter of the men became cadet officers, the remainder, sergeants.

At graduation, all men received the same rank, second lieutenant, and entered one of the army's several branches (e.g., infantry, engineers) or the air force, which at this time did not have its own academy. Men almost always stay in their service, and tend to stay in their branch, for the rest of their professional lives. Most young officers earn advanced degrees and seek a variety of assignments in military schools, command, and staff positions.

Within three years, 8% of the class members were dead (two-thirds of them killed in the Korean War, which began only weeks after graduation). By 1960,

20% of the class had resigned for various attractions outside — and frustrations inside — the army (Butler 1971a). Nearly all those who remained in the military through the 1950s would stay for 20 years (or more) in order to retire with benefits.

While promotion of young officers is nearly automatic through the rank of captain, being determined primarily by amount of time served, early promotion to the rank of major or lieutenant colonel is regarded as an indication of special merit. Of the class of 1950, 6% made lieutenant colonel by 1964, and these men were more likely than their classmates to make general. In fact, speed of promotion to each rank predicts the likelihood and speed of promotion to all subsequent ranks. The sorting of men begins early, separating those who will reach the top from those who will not, as occurs in many other occupational hierarchies (Mazur, Mazur & Keating 1984).

Between 1966 and 1972, about one-third of the men still on active duty were selected to attend a war college, nearly always after promotion to lieutenant colonel. For war college graduates promotion to colonel was virtually certain. Although not a formal requirement, it seems that no one has been selected for general since World War II who has not graduated from a war college. In army jargon, war college is an essential "ticket punch" on the route to general.

Many of the classmen served in Southeast Asia during the Vietnam War, but only seven were killed, reflecting the relative safety of their higher ranks. Nearly everyone in the class who remained in the military had been promoted at least to lieutenant colonel by 1970, the first year in which they were eligible for retirement with benefits. Mandatory retirement year (with few exceptions) was 1978 at the lieutenant colonel rank, 1980 at the colonel rank, and 1985 at all general ranks. Eight percent of the graduates of 1950 became generals (the first ones in 1971), making them by this measure one of the most successful of modern West Point classes. Most of these generals remained on active duty during the 1980s, filling the highest ranks of the American military.

Methods

DATA

New findings to be reported here depend on important improvements in method from that used by Mazur, Mazur and Keating (1984). Their original study was based on published sources of data. West Point's student yearbook, *The Howitzer* (1950), contained cadets' portraits and indirect measures of other variables including height and athletic prowess. The academy's annual *Register of Graduates and Former Cadets* (1964, 1980) listed records of promotion, but the 1980 edition of the *Register*, the latest available for that study, did not contain final ranks for the most successful graduates, those still on active duty in 1980.

These original data are merged with new data obtained for the present study from a questionnaire mailed in 1990 to 539 men from the class of 1950 for whom recent addresses were available. This was a fairly complete mailing to the surviving members of the class. After two follow-up mailings, we received 434 completed questionnaires, an unusually high response rate of 81%, no doubt because of the participation of West Point's Association of Graduates in the

project. Of 416 classmen who served 20 or more years in the military, 334 (80%) returned questionnaires, including virtually all the generals. The 16-page questionnaire asked about promotions, family background, education, career motivations, fertility, and family relationships.

VARIABLES

We are interested in predicting a classman's military rank attainment by the time of retirement, as reported in his questionnaire. Considering only the 337 respondents who served 20 years or more in the military, the distribution of final ranks is, in ascending order, major (1%), lieutenant colonel (26%), colonel (56%), brigadier (one-star) generals (7%), major (two-star) generals (5%), lieutenant (three-star) generals (3%), and "full" (four-star) generals (2%).

Elsewhere a considerable number of independent variables, including several measures of family background, were tested as predictors of military rank (Mazur, Mazur & Keating 1984; Mazur & Mueller in press; Mueller 1991).

Here we restrict our models to the following independent variables, which are of particular theoretical or empirical interest.

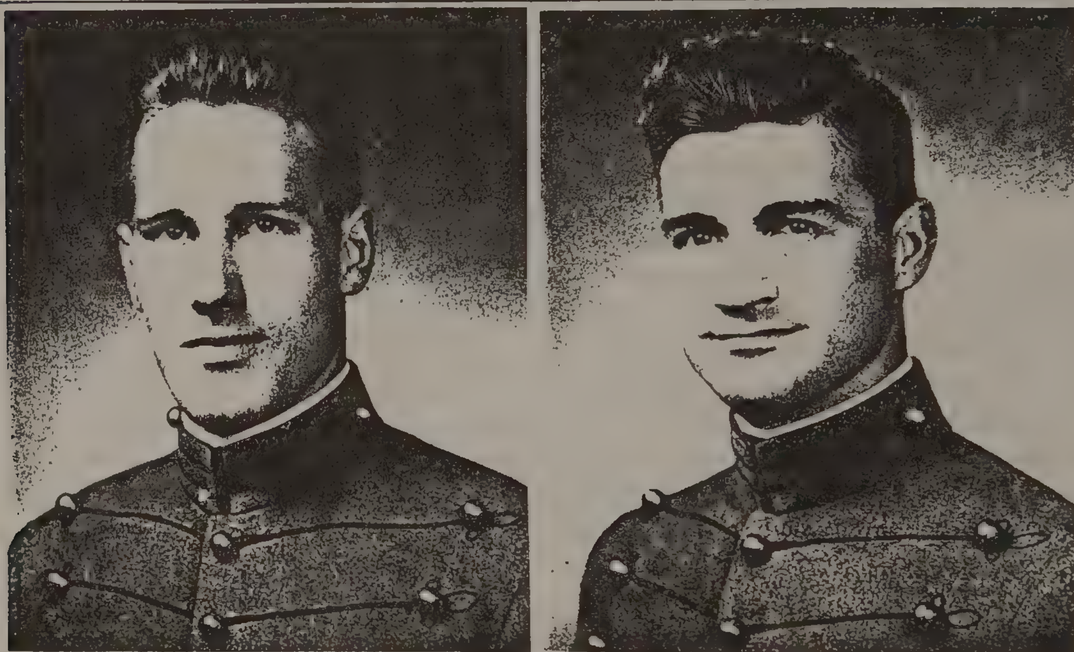
Face

Facial dominance was measured for all cadets who remained in the military for 20 years or more. Their yearbook graduation portraits (*Howitzer* 1950) were copied on slides for projection in front of 20 to 40 judges (usually undergraduate classes), who independently rated faces on a seven-point scale of dominance-submissiveness (1 = very submissive, 4 = neutral or undecided, 7 = very dominant). Judges were instructed that a dominant person tells other people what to do, is respected, influential, and often a leader; submissive or subordinate people are not influential or assertive and are usually directed by others. On 86% of the rated slides, at least half the judges' choices fell within two adjacent scale points, indicating more clustering than would be expected if the choices were uniformly distributed across the seven-point scale. Scores on the 14% of the slides that did not meet this cluster requirement were dropped as unreliable (the median of those dropped, however, did not differ from the median of the rest). The median score for each slide was taken as the value for *face*. These values ranged from 2 (moderately submissive) to 6 (moderately dominant) with a median value of 4 (neutral) and a mode of 5 (slightly dominant). Smiling, especially broad smiling, is known to lower facial dominance (Keating, Mazur & Segall 1981a, 1981b). In our sample, slight smile led to a 0.3 score point decline, broad smile (teeth visible) to a 0.7 score point decline. Dominance scores were adjusted accordingly (Mazur, Mazur & Keating 1984). Figure 1 displays cadet faces exemplifying a range of dominance scores.

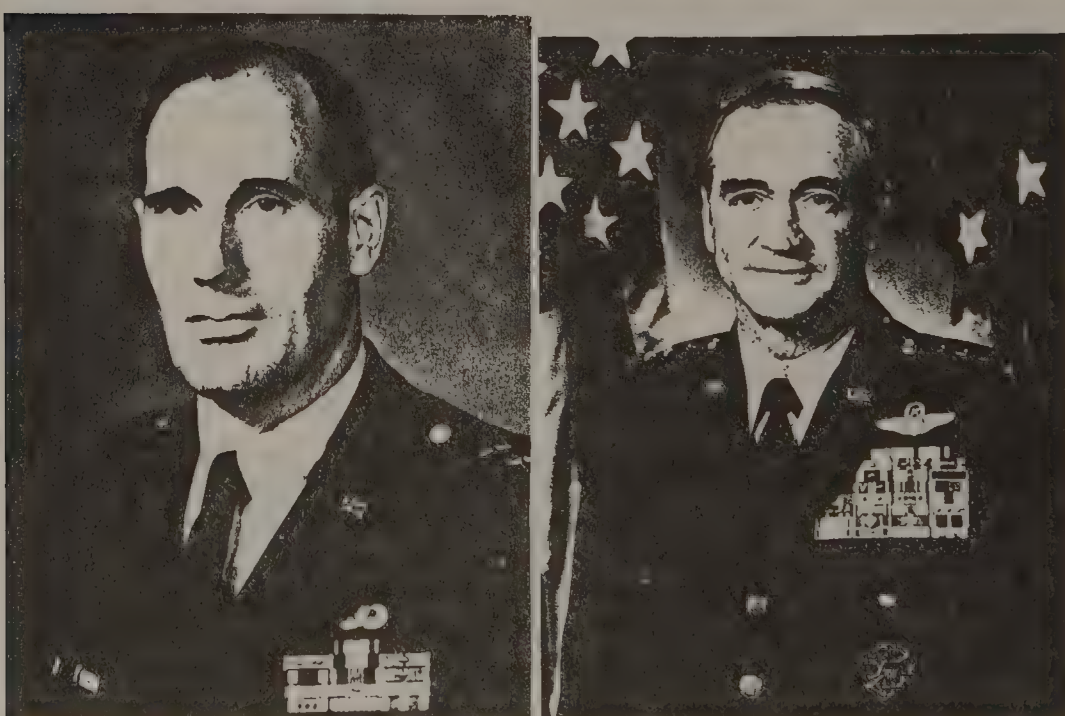
Athletic

By common standards, nearly all cadets are athletic and well proportioned physically, since these qualities influence admission to the academy. In order to mark the most athletic of these men, a dummy variable *athletic* was scored as 1 for the 16% of the classmen listed in *The Howitzer* as participants on a collegiate team in their senior (varsity) year; the remainder of the class was scored 0.

FIGURE 1: Cadets of Varying Facial Dominance Who Became High-Ranked Generals, as Cadets and at the Peak of Their Careers[a]

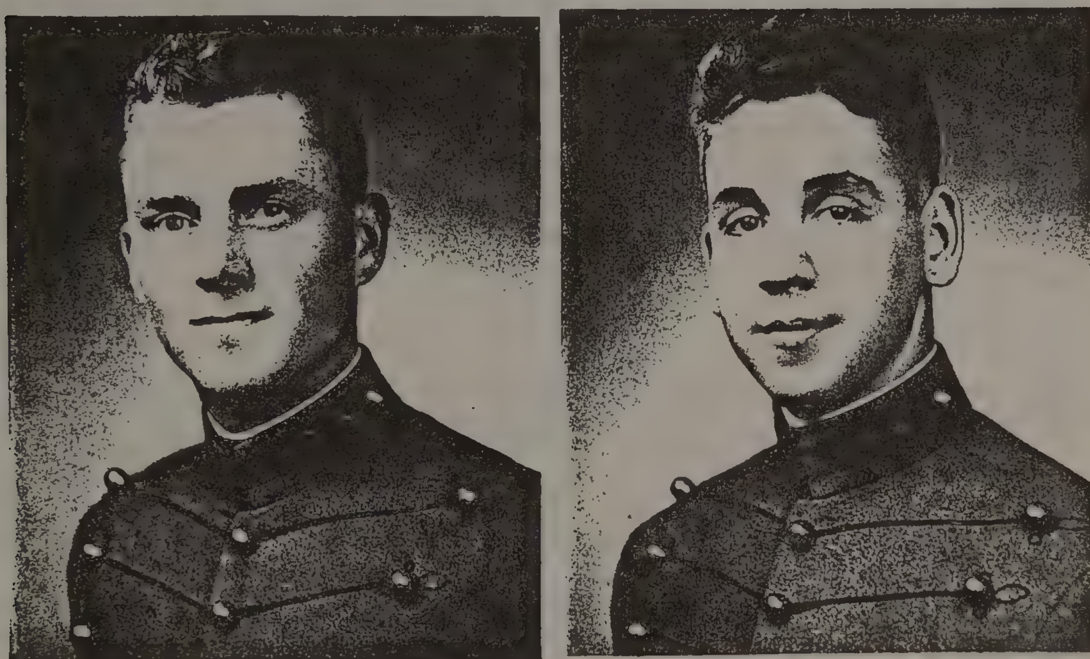


Wallace Hall Nutting | Charles Alvin Gabriel



[a] Faces are arranged from most to least dominant. The cadets with their ranks and final positions are, from left: General Wallace Nutting (*face* = 6), commander-in-chief, U.S. Readiness Command; General Charles Gabriel (*face* = 5), Chief of Staff, U.S. Air Force;

FIGURE 1: Cadets of Varying Facial Dominance Who Became High-Ranked Generals, as Cadets and at the Peak of Their Careers[a] (Continued)



John Adams Wickham Jr. Lincoln Faurer

[a] General John Wickham, Jr. (*face* = 4), Chief of Staff, U.S. Army; Lieutenant General Lincoln Faurer (*face* = 3), head of the National Security Agency. Portraits as cadets are from *The Howitzer 1950*, portraits as officers are from the U.S. Army Military History Institute and the Center for Air Force History.

Athletic is not simply a measure of physique, since it must include other personal and symbolic qualities associated with athletic prowess.

General Order of Merit

Until 1978, every graduate of West Point was given a number at graduation to indicate his "general order of merit" (GOM) within the class (*Register* 1980), the lower the better. Basically a performance measure, this aggregate evaluation combines academic grades, peer and instructor ratings of leadership and military aptitude, and physical education grades. At least until midcareer, GOM is known to be related to subsequent promotion (Butler 1976; Mazur, Mazur & Keating 1984).

Friends

Mazur, Mazur and Keating (1984) found that a crude measure of cadets' sociability predicted high military rank, so we include it here. There is a description approximately 50 words long of each graduating cadet in *The Howitzer*, typical of student yearbooks. The 41% of cadets whose descriptions made specific reference to their "friends" were scored 1 on the dummy variable *friends*; others were scored 0.

War College

Graduation from a war college is an essential step in becoming a general. Attendance at any one of five equivalent war colleges and date of graduation were coded from the *Register of Graduates* (1991). We do not treat war college attendance like the other independent variables, regarding it instead as a screening or interaction variable that specifies the pool from which generals will be drawn.

Parents' Education

Social class background, usually measured by parental education, is an essential feature of traditional models of status attainment. Here the father and mother are coded as having graduated from college or not. In addition, father is coded as having been a military officer or a West Point graduate himself.

Branch

Some of the army branches (such as infantry and armor) in combat can bring closer physical contact to an adversary than others (such as artillery, including coastal artillery, corps of engineers, signals, and ordnance) or the air force, and may, therefore, attract men who are more aggressive and, therefore, may look more dominant. In addition, career chances may vary among branches or services.

Analysis

We have nothing to add to Mazur, Mazur and Keating's (1984) results on early promotions, from West Point cadet officers up to the rank of major. Here we

analyze promotions to the middle and higher ranks: to lieutenant colonel and the various grades of general. We restrict our analysis to the classmen in our sample who remained in the service for 20 years or more, i.e., to those who made a life commitment to a military career. Nearly all (save four men) achieved the rank of lieutenant colonel or higher. Due to a lack of reliable dominance scores (see the discussion of *face* above) in 45 cases, we are left with a final sample of 289 career officers.

We recognize two aspects of promotion: (1) Does a man ever rise to a higher rank? (2) If so, how quickly does he do it? The two aspects are connected by the fact that in an organization in which promotion is based on merit, factors that make a promotion more or less likely may be the same as those that accelerate or slow down the speed of promotion.

Mazur, Mazur and Keating (1984) compounded these two aspects by comparing men who had attained different ranks by a given date (1964 and 1980). We use a different analytical strategy here. In general, there are two approaches to investigating the dynamics of these military careers. In one approach we treat the major transitions in a military career separately. For example, the promotion from lieutenant colonel to colonel was a virtual certainty for those who graduated from a war college. It was obtained by 53% of lieutenant colonels who did not. Being promoted to colonel for a nongraduate of war college is purely a reward — his career cannot proceed any further. Being admitted to war college, on the other hand, is not only a reward; it is an investment in that man. Less than half of the war college graduates, on the other hand, were promoted from colonel to brigadier general. Thus, each promotion poses different circumstances.

In the second approach, we investigate all of a man's promotions, counting from different base ranks onward; that is, we count total promotions above the level of colonel, brigadier general, etc. This can be justified on the grounds that the more capable a man is, the more often he will convince promotion boards, school selection boards, and command selection boards of his worth. Thus, subsequent promotions can be viewed as cumulative steps in one's career process and may be treated as an interval measure of status attainment from a given level.

Both approaches pose methodological problems.

In the first approach, if we investigate each promotion independently, we could model it as a transition process with two risks: promotion and retirement. The problem here is that the two risks are not independent, the censoring process — premature retirement — eventually depending on the distribution of the promotion risk. Officers are well aware of their chances of obtaining another promotion.

A man of the class writes about the promotion to colonel: "You are considered each time the promotion board meets for the next rank. And, since the promotion board normally meets once a year, you are considered each year. . . . If you are passed over to lieutenant colonel or to colonel . . . , in effect, you are dead. Forget the next two years. . . . For instance, the most common passover to colonel is caused by a poor efficiency report (maybe just "excellent" instead of a "max") as a battalion commander. Everything else was okay, or you wouldn't have made lieutenant colonel. During the next 2 years, nothing you

can do will change that lousy command OER (Officer Evaluation Record) in your file. Your best bet: retire."

Another classman writes about the promotion to brigadier general: "Not only is the promotion board to brigadier general given strict criteria, but all colonels in the 'zone' are aware of the criteria which [are] always published. . . . I think I was competitive for brigadier general for about 1 year, during and just after my tour as XXX. . . . After the next board met, and I wasn't selected, I knew that my chances were zero."

We may conclude from these statements that most men who retired before they reached the mandatory retirement age of their rank (28 years of service for lieutenant colonels, 30 years for colonels, 35 years for all grades of general) did so, among other reasons, because they — more or less correctly — assessed their chances of promotion to be low. We may assume that they would have stayed longer had their chance of promotion been better. On the other hand, many men with little or no chances of promotion may have stayed until the end because of a lack of attractive alternatives. The interdependence of the two risks is, however, one-sided: the probability of premature retirement may have been influenced by perceived promotion chances, but not vice versa. Actually, none of the factors considered here as affecting chances of promotion on any level was a predictor for premature retirement.

The alternative, modeling the process as a one-risk process means effectively treating all men who were not promoted as if they had stayed until mandatory retirement age. Since every man in a given rank is being considered for promotion throughout several years, application of a mover-stayer model — assuming unobserved heterogeneity with respect to promotion chances — would be highly questionable, especially if we assume that, in the end, all movers have moved and all stayers have stayed. On the other hand, neither is the assumption plausible that all men are movers, some of whom, however, were not allowed to move but might have moved had the demand for officers on the next rank been greater at the time. Even in wartime there will always be a substantial proportion of men in any rank who will not be promoted further. Taking all things together, modeling career transitions as a process with two independent risks might be a lesser distortion of reality after all. In fact, the estimated factor effects were not different for the one-risk and the two-risk models.

A third possibility would be simply to compare all those who were promoted with those who were not by a multivariate logistic regression model. By doing so we would circumvent the problems caused by the intricate censoring process but would give away information about the time dimension of the process: the speed of the career. As for many other life events, the same factors that increase the chances of promotion may accelerate its occurrence. These factors also may increase the chances of subsequent promotions.

For the second approach, the choice of an appropriate model is not obvious either. Since, here, we are not interested any more in transitions from or to a single state = rank, but rather in final career outcome, total number of subsequent promotions, as seen from some rank level already achieved, would be the dependent variable. All possible promotions take place within a fairly similar time span — all promotions save one to brigadier general and 80% of all

promotions to major general took place before 1978, when lieutenant colonels had to retire; all promotions save one to major general and 80% of all promotions to lieutenant general took place before 1980, when colonels had to retire; general officers of all ranks could stay until 1985. Thus, total number of subsequent promotions is a very good indicator not only of final outcome but also of speed of career.

The appropriate model for analyzing these count data, however, is not a point process (Cox & Isham 1980), because after any promotion there is an official minimum waiting time of two years (there may be exceptions for the highest ranks), a substantial proportion of total average waiting time during which no promotion can occur, but premature retirement can; and because the number of events that one person can experience is limited: no one can obtain promotion beyond full general.

We chose the following strategies:

We investigated single transitions with a two-risk (promotion and retirement) model, but we look only into the factors affecting the risk of promotion. Reasons when to retire — see quotations above — may entail, in addition to the perceived promotion chances, a variety of factors from family situation to labor market conditions that lie outside the focus of this study. In fact, none of the factors considered in this study predicted time of retirement. Since the underlying time process (annual promotion board meetings) is discrete, there is no theoretical reason to prefer one parametric model over the other. In particular, there is no reason to assume that one parametric model is the appropriate one for all transitions considered here. Therefore a proportional hazard rate model as described by Cox (1972; Cox & Oakes 1984) is the model of choice. We will consider graduation from war college, promotion from major to lieutenant colonel (which all save four men in the sample obtained), from lieutenant colonel to colonel, from colonel to brigadier general and from brigadier general to major general. The last promotion is tantamount to accession to the military elite nucleus. The crucial condition of proportionality of the influence of covariates is fairly well fulfilled (see the discussion of results).

In addition, we compared with a logistic regression those who made the transition with those who did not.

For analyzing the total number of promotions as seen from various ranks onward we simply chose multivariate OLS regression with the log of total number of promotions as the dependent variable. For the interesting ranks (colonel with war college, brigadier general, major general — all lieutenant colonels with war college became colonels, all without could not become more), the total number of promotions possible range from 0 to 4, 0 to 3, and 0 to 2, respectively. For that many levels in the dependent variable, OLS methods can give sufficiently robust results (Bentler & Chou 1987).

Results

Measures of parental education including father's military background are unrelated to any career variable (same findings in Butler 1971b and Janowitz 1971) and were therefore dropped from subsequent analysis.

TABLE 1: Correlations (Gamma) between Dichotomized Independent Variables

	Athletic	General Order of Merit	Friends	War College
Face	.11	.12	-.04	.01
Athletic		.12	-.17	.22
General order of merit			.05	-.42**
Friends				.06

(N = 289 to 334)

* $p < .05$ ** $p < .001$ (chi-squared test)

Career chances after graduation from war college were better for classmen in the air force than in the army (17 out of 27 became generals, as compared with 39 out of 113), perhaps because, in the post-Vietnam era, the air force was not cut back in size as much as the army. No variable considered here nor any other data obtained in the survey predicted a man's entering the air force. Also, all effects on career dynamics reported below could be observed for air force and army alike. Classmen who entered "combat" branches within the army (infantry, armor) had the same facial dominance scores as men opting for one of the other army branches. No such differences could be observed among those still on active duty 20 years after West Point, nor among war college graduates, nor among generals. Likewise, career chances were equal for all army branches — a closely watched issue for officers and personnel planners anyway. Consequently, membership in a particular army branch or the air force was dropped from further analysis.

Table 1 contains a correlation matrix of the remaining independent variables using gamma, which is insensitive to marginal distributions. Variables are dichotomized as indicated above or, in the case of *GOM* and *face*, at their medians. The only significant gamma is between *GOM* and *war college*, indicating that men with lower (i.e., better) GOM rankings were more likely to graduate from war college. Otherwise there is no multicollinearity to complicate the interpretation of regression coefficients.

DISCRETE PROMOTIONS

Graduation from war college is a prerequisite for being promoted to general and virtually guarantees promotion to colonel. Admission to war college effectively separates officers into two career "channels" (a concept we have developed elsewhere: Mazur & Mueller in press): the one eventually leading to general's stars, the other not.

TABLE 2: Coefficients of Dichotomous Covariates for Transition to Ranks from Rank Below and to War College Graduation according to the Proportional Hazard Rate Model

+ War college graduates only
- Nongraduates of war college only

* $p < .05$ ** $p < .001$

Following our hypothesis that facial dominance might — deliberately or not — be regarded as an important factor for any high leadership position but irrelevant for "middle management" positions, we expect that *face* may influence a man's chances to be admitted to war college, and for the sequence of promotions from lieutenant colonel to four-star general in the channel opened by that admission, but may be irrelevant for the promotion from lieutenant colonel to colonel for those men who did not go to war college.

Accordingly, proportional hazard rate models were estimated for admission to war college and for promotion from major to lieutenant colonel for all men in the sample, and for all five promotions from lieutenant colonel to four-star general in the channel for war college graduates. In addition, a proportional hazard rate model was estimated for the promotion from lieutenant colonel to colonel for those men who did not go to war college. Base line estimates were made according to Breslow (1974); given the lack of a generally accepted goodness-of-fit test statistic for these models (Andersen et al. 1992:208-15; Fleming & Harrington 1991:92-94; Lin, Wei & Ying 1993; Lin & Wei 1991) we confined ourselves to graphical testing (see below); the program was TDA written by Goetz Rohwer of the University of Bremen.

The effect of *face* in the channel for war college graduates is not significant for any single transition, but the effect is always in the predicted positive direction (sign test: $p < .05$). *GOM,* while being a powerful predictor of graduation from war college, shows an inconsistent effect otherwise, as does *athletic.*

Having had *friends* as a cadet displays the same consistently positive effect on transition rates as *face* in this channel. *face,* on the other hand, has no effect on promotion from lieutenant colonel to colonel in the other channel (see Table 2).

[a] Graduation from war college: all men serving for 20 years and more; promotions: all men in rank below, calculated for actual risk population — excluding prematurely retired men.
Submissive (Sub.) = *Face* score at or below median;
Dominant (Dom.) = *face* score above median.

\+ War college graduates only
\- Nongraduates of war college only
* No further transitions

The estimated survival functions for all five transitions in the career channel for war college graduates, comparing men with *face* scores above the median with those below it, show that in every rank, at nearly every point in the respective interval, men with high *face* scores were subject to higher transition rates than men with low scores (the difference between proportions surviving is monotonically increasing, as required by the proportional hazard rate model). Given the strong positive correlation between early promotion to a rank and the chances of another promotion, the differences between single survival functions even understate the real advantage high *face* scores secured to men in this career channel. For promotion from major to lieutenant colonel, for admission to war college, and for promotion from lieutenant colonel to colonel for men who did not attend war college, this does not apply (see Table 3).

In addition, we used logistic regression analysis of discrete promotions of single transitions, comparing all those who experienced the transition with those who did not.

Since all save four men in the sample obtained promotion to lieutenant colonel, and since graduation from war college virtually assured promotion to

[b] Three distinguished professors at the academy or other military colleges were promoted brigadier general upon retirement in the late 1980s. These promotions were not considered here.

colonel and is an essential step toward higher rank, at midcareer we focused on admission to war college from any rank (usually lieutenant colonel). GOM is the only independent variable significantly related to war college admission (logistic partial correlation coefficient $R = -.21, p = .001$). Also, *athletic* ($R = .13, p = .003$) and *GOM* ($R = -.07$, $p = .04$) were moderately strong predictors of promotion to colonel for men who did not attend war college. Neither *face* nor *friends* played any role for these two transitions.

Since only war college graduates become generals, our regression for promotion from colonel includes only men who graduated from war college ($N = 140$). Among these, only *face* is a significant predictor of promotion from colonel to brigadier general ($R = .12$, $p = .05$). Among brigadier generals, *face* is the only predictor of promotion to major general that approaches significance ($R = .12, p = .10, N = 51$). The number of men at even higher ranks is too small to expect significant effects, and there are none for promotion from major general to lieutenant general ($N = 31$). However, for promotion from lieutenant general to full general ($N = 16$), both *face* ($R = .09$, $p = .13$) and *friends* ($R = .19$, $p = .09$) approach significance.

NUMBER OF PROMOTIONS

Figure 2 shows the average number of promotions (from a base rank) as a function of facial dominance. There are three curves, corresponding to three base ranks: colonel, brigadier general, and major general. For example, the solid line shows the average number of subsequent promotions for colonels at each value of *face*. Clearly, the more dominant a colonel's face, the more future promotions he enjoyed. The other curves give a similar picture. (No men with *face* values below 3 were promoted to general, so the graphs showing promotions from brigadier general and major general begin at *face* = 3.) The graphs show men with *face* scores of 6 receiving .3 to .8 more promotions than men with *face* scores of 3.

The number of promotions from the ranks of colonel, brigadier general, and major general was regressed on the independent variables. For example, for all men who reached the base rank of colonel, we used OLS regression to predict their number of future promotions. Standardized coefficients (betas) and their significance levels are shown for each base rank in Table 4. Since men who do not graduate from war college by the time they are colonels have no chance of further promotion, we include only war college graduates in the regression from the base rate of colonel. Of 140 colonels who had graduated from war college, only 56 men reached brigadier general and 31 attained major general rank, and so significance tests are not equally powerful across these regressions.

Regression results in Table 4 vary considerably across base ranks. The same four independent variables explain more variance (R^2) in promotions from brigadier general and major general than in promotions from colonel.

Face is a strong and significant predictor of the number of promotions from colonel and becomes an even stronger predictor of future promotions for brigadier generals. *Face* remains a sizable predictor of promotions from major general although there are only 31 subjects in this final regression.

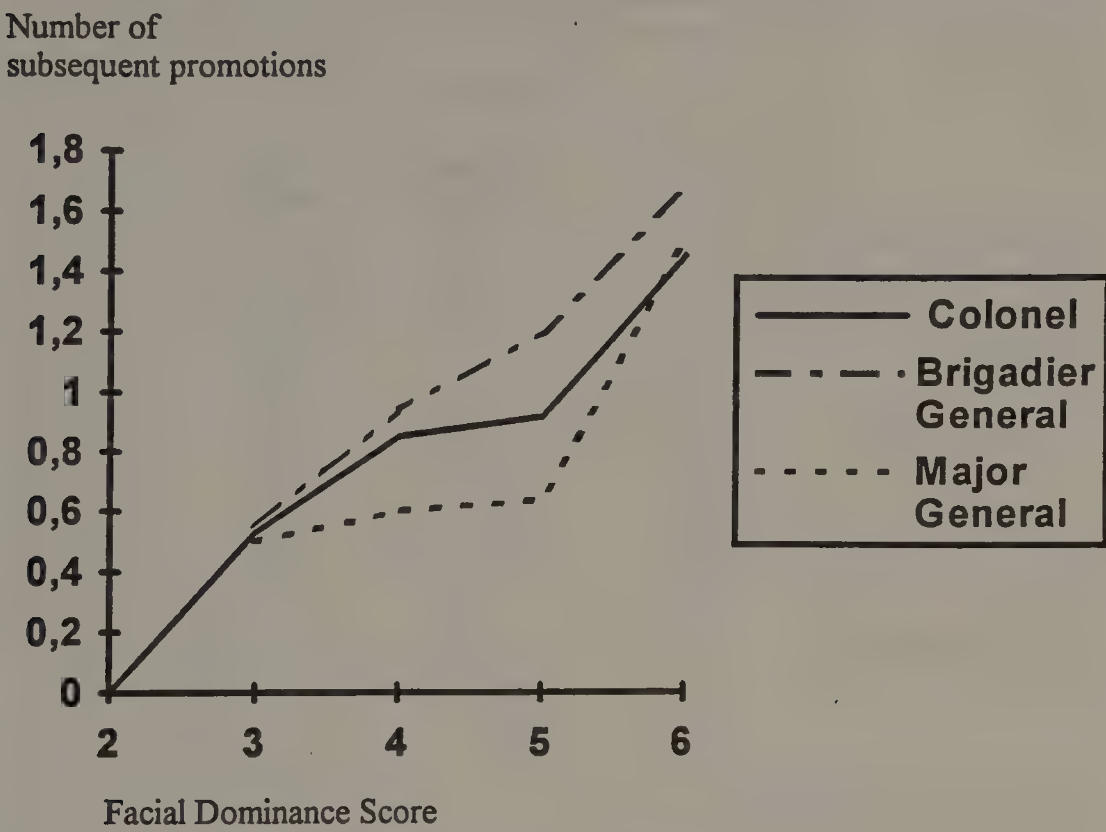
Varsity athletics (*athletic*) approaches significance in predicting promotions from brigadier general ($\beta = .24$), but given the small number of brigadier generals, its effect does not reach significance ($p = .07$). It is neither a strong nor a significant predictor of promotions from colonel or major general.

GOM has little predictive power when the promotion pool is limited to war college graduates. A reason could be that men with better GOM are more likely to enter war college (Table 1), thus restricting the range of the variable. This effect, however, if any, is weak: lower quartile and median and upper quartile of GOM for all classmen as well as for all lieutenant colonels was 48, 64, 83; for all war college graduates, 44, 58, 73; for all generals, 44, 57, 71.

Friends is a modest predictor of future promotions from all base ranks, significant or very nearly significant for promotions from colonel and brigadier general. Considering the extreme crudity of this measure of sociability, it is noteworthy that it shows any effect at all.

Together, the independent variables explain more variance in promotions once the pool is limited to war college graduates. While *GOM* loses its predictive power here, *face* and to a lesser degree *friends* become more important. *Face* is a sufficiently strong predictor for the career potential of colonels and

FIGURE 2: Number of Promotions from Each Rank, by *Face*[a]



[a] 20+ years of service, war college graduates only. Values for *face* = 2, for *face* = 6 from brigadier general, and for *face* = 3 and 6 from major general, are based on very small samples of size 4-9. Remaining values for brigadier general and major general, and for *face* = 6 from colonel, are based on samples of 10-19. Remaining values for colonel are based on samples of 103.

brigadier generals that it reaches significance despite the small sample. Figure 2 leaves little doubt that *face* is important in promotion from major general, too.

Event history analysis and logistic regression analysis of discrete promotions are less powerful and show fewer significant effects than OLS analysis of total promotions, but the single event effects that do appear are consistent with OLS results. Both point to *GOM* as an important predictor of admission to war college but not of later advancement within the pool of war college graduates. Both show *face* to be unimportant at middle rank, but after graduation from war college, both show *face* to be consistently the most important predictor of high rank.

Discussion

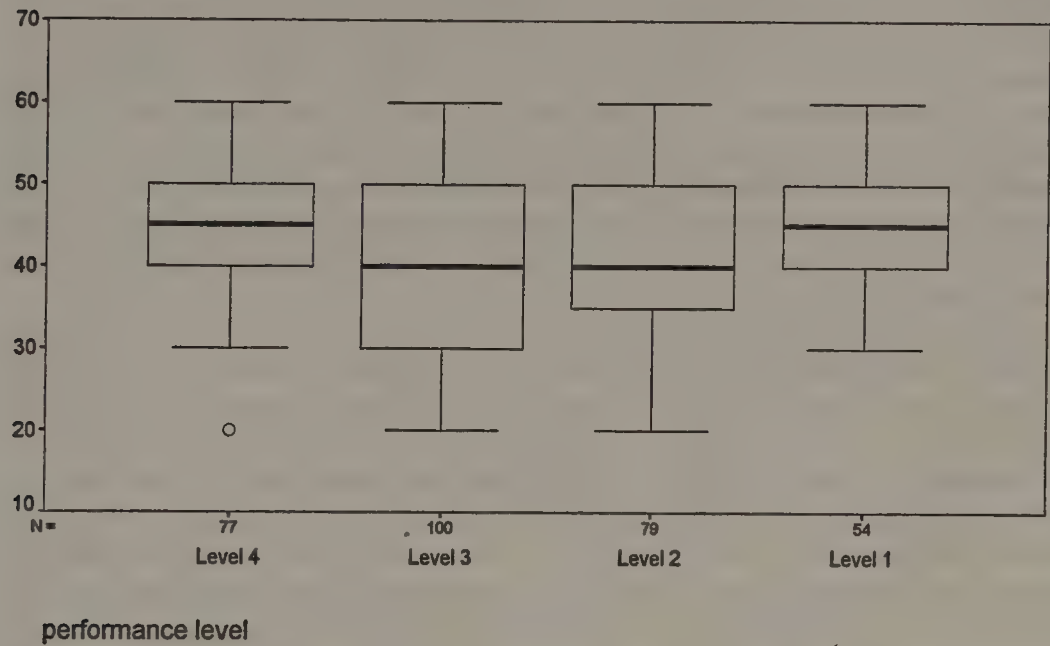
Improved methods show that cadets' facial dominance, measured from their West Point graduation portraits, predicts military rank 20 years or more later. The finding is theoretically important in part because it allows us to evaluate hypotheses raised by Mazur, Mazur and Keating (1984) at the conclusion of their research.

First, we can reject any suggestion that dominant appearance in a graduation portrait is the effect, rather than the cause, of attaining the status of cadet officer while at West Point. The fact that these portraits correlate with rank 20+ years later, as well as at West Point, while the status as cadet officer does not correlate with rank in late career (Mazur, Mazur & Keating 1984; see also Janowitz 1971), makes the causal direction unambiguous.

Second, we can also reject the hypothesis that in middle age, physical features lose their relevance for hierarchical placement.

Third, it was also hypothesized that *face* failed to predict future rank because middle-aged men no longer look like their graduation portraits. It is certainly true that looks change with age. But since *face* does predict the highest level promotions, its failure to predict earlier promotions must be due to some other factor than the timeliness of the portrait. This conclusion is buttressed by a supplementary study of 30 classmen who provided us with portraits taken in

FIGURE 3: Facial Dominance by Performance Level



Performance levels:

Level 4: no war college; final rank = lieutenant colonel
Level 3: no war college; final rank = colonel
Level 2: war college graduates; final rank = colonel
Level 1: war college graduates; final rank = general

middle age (average year = 1972) that could be compared to their cadet portraits (Mazur & Mueller 1993). Middle-age portraits were scored for dominance by the same method used on the cadet portraits. Although poses, dress, and formats of the middle-age portraits are considerably more variable than those of cadet portraits, the correlation between dominance ratings of portraits taken 20 years apart is gamma = .44 (p = .04). Men who looked dominant as cadets tended to look dominant in middle age as well. This finding accords with the stability over a lifetime reported for other facial impressions like babyfacedness and attractiveness (Zebrowitz & Montepare 1992; Zebrowitz, Olson & Hoffman 1993).

Fourth, we can also discard the hypothesis that the absence of an effect of facial dominance on early and middle career is due to a sampling bias: that the uninterrupted effect of facial dominance was masked by the — on the average — greater facial dominance of West Point graduates than of their far more numerous competitors who obtained their commission elsewhere.

Apparently the percentage of West Point graduates among war college graduates was not much lower than the percentage of West Point graduates among generals: that is, in the 40-50% range (Atkinson 1989, quoting official sources; Moore & Trout 1978). On the other hand, for the men in our sample, the most restrictive filter in the long sequence of career steps was admission to war college: of those eligible, only 39% passed it (only the last filter of all, the one to full general, with a 35% chance for those eligible, was even harder to pass). If facial dominance were important also in midcareer, then, even if West Pointers look more dominant than other candidates, its effect should have become visible in our sample, at least at the transition to war college. Since it was not, we conclude that the effect existed only at the academy and at the top of the hierarchy.

This leads us to favor the remaining hypothesis, that facial appearance is a leadership quality that is more important for some promotions than for others because it signals qualifications that are more important for winning in primary group contests. Consequently, it should be more important when those recommending promotion know the candidate personally. Such is the case both at West Point, where the decision is based on evaluations by cadets and tactical officers, and in promotion to the highest ranks, attained by a few men toward the end of their careers, when the small pool of candidates is again personally known to those in judgment. At midcareer, their physical appearance is not an important factor compared to their records, even though the portraits accompany promotion files.

Academic attainment, as measured by GOM, is the only one of our four independent variables that is conventionally regarded as an important determinant of promotion in merit-based bureaucracies, which the modern military certainly is. It is puzzling that at the highest ranks, this indicator of technocratic competence loses its prior relationship to promotion. Since the range of GOM is only slightly restricted by the sequence of filters in this channel, we may conclude that after graduation from war college, for high positions in the hierarchy, leadership qualifications not measured by GOM become more important. At the same time, factors that seemingly ought to be irrelevant in a meritocracy — facial dominance, athletics, and friendliness — increase their relationship to promotion.

The best-measured of our four independent variables, GOM, is based on four years of college achievement, yet it is unrelated to promotion to the highest ranks. In contrast, the other variables are operationalized in ways that seem barely adequate: *face* is measured from a yearbook portrait taken 20 or more years before the highest rank is attained; *friends* is coded from a 50-word profile of each cadet in the yearbook; and *athletic* measures some ambiguous combination of physique, athletic prowess, team spirit, and in the case of lacrosse or football, school glory. It is remarkable that they relate to anything, yet these are the variables most predictive of final promotions. It is a compelling hypothesis that improved measures of these variables would produce far stronger relationships than are reported here. If true, then the effect of these variables on promotion is substantial.

What is the social mechanism behind the positive effect of facial appearance on status attainment at the academy and at high levels of the military hierarchy, but not at the low and middle levels?

Virtually all studied species of nonhuman primates use facial gestures to signal social status (dominance and submissiveness) (Smuts et al. 1987). These gestures help to regulate relationships among conspecifics by settling conflicts without violence or with limited violence. Homologous human facial gestures have been shown to exist and to be reliably and uniformly interpreted in many cultures (Keating, Mazur & Segall 1981a, 1981b). Characteristically, conflicts of all sorts are settled by an escalation of warnings, threats and the application of force with increasing intensity: the outcome is decided once one of the contestants decides not to move up the escalation ladder any further. Conflict resolution thus crucially depends on the perception and credibility of escalation threats. Cues for the credibility of escalation threats may be called signals.

Facial dominance as analyzed in this study seems to signal the potential for as well as the intention of escalation (for a detailed discussion of facial dominance as a biological signal see Mueller & Mazur 1995; see also Mazur 1985): strong jaws may indicate a heavily built skeleton, and therefore superior physical strength. A broad prominent forehead with strong eyebrow arches may indicate enhanced ability to absorb hits. The conventional signals that can be found in dominant looking faces seem to include several gestures observed in many nonhuman primates and humans as well when preparing for a fight (Harper 1991): thin lips, withdrawn corners of the mouth, lowered eyebrows with partially closed eyes (in order to protect them against injuries), withdrawn ears, making them appear smaller. Conversely, people with facial features typical of infants (large eyes, high thin eyebrows, round face, small nose bridges — "babyfacedness") are perceived as warmer, weaker, submissive (Berry 1990). Babyfaced people describe themselves as less aggressive (Berry 1991). At present, however, our knowledge is very limited about the functional contribution of such anatomical and gestural features to the overall perception of facial dominance. Also, for our sample we have only the scores of perceived facial dominance from the ratings.

Our data suggest that facial dominance did not function as a relevant qualification for junior or middle rank positions nor for admission to war college (as Collins & Zebrowitz 1995 in a small sample of men who had served in the military for some years — mainly from age 20 to age 25 — found no correlation between babyfacedness and number of promotions), but did so function for promotion to cadet ranks at the academy and for promotion to the top positions in the military hierarchy. There must be some relation between dominant looks and the abilities it signals. If the selection of persons for an important position is made dependent on many sensible indicators for competence, then adding a criterion that is completely uncorrelated with competence will inevitably decrease the average quality of the selection. Therefore, if selection to the top ranks is made also on grounds of perceived facial dominance, facial dominance must be a useful feature of a cadet or a general.

These findings still leave room for various interpretations of the social meaning of this set of basically biological signals, which evolved in an environment of long ago.

Typically, conflicts within modern organizations are not decided by threat or application of physical force; such behavior is severely sanctioned. Therefore, along the line of the "novel environment" approach (Barkow, Cosmides & Tooby 1992), it could be argued that while there is a universal, even biological, basis for facial dominance signals, in the social reality of modern meritocratic organizations they carry some other meaning.

Perhaps promotions into the military elite, the top levels of the hierarchy, go preferentially to those who present themselves as tough warriors, even if the management of modern warfare requires quite different abilities. Embodying the ideals of the hierarchy in such a direct way may also help to prevail in primary group contests within the organization. This would be an application of Moore and Trout's (1978) "visibility" theory in a symbolic interactionist tradition: Using a biological communication channel in order to send a culturally mediated message, men present themselves in conformity with the values of the established hierarchy that they want to join. Several empirical findings in our sample, however, make it difficult to defend this interpretation.

Such an interpretation first must assume that, in this particular professional group, facial appearance is prized and possibly rewarded. This much definitely is the case — to men in our sample the findings of this study neither came as a surprise nor as an offense (see also the opening discussion of this article).

On the other hand, a smile, in particular a broad smile, decreases the facial dominance score awarded by raters and, therefore, probably decreases perceived facial dominance, too. Mazur, Mazur and Keating (1984) found that broad smile (with teeth visible) decreased facial dominance score by 0.7 points (see the discussion of variables). The portraits in the graduation yearbook were well prepared and carefully taken, and furthermore, we may assume that, as in other American colleges, graduates had a chance to select their portraits for publication from several photos taken. We should then expect that ambitious men, those who had already attained a cadet officer rank, as well as those who wanted to rise high, were more inclined to present themselves on the portraits to be as dominant as possible and therefore should have avoided posing or selecting portraits with a broad smile altogether. There were however, no differences in the distribution of broad smiles over cadet ranks. Cadet officers displayed broad smile not less frequently than cadet sergeants (see Table 5). Likewise, there was no difference between future officer ranks: future lieutenant colonels, colonels, and generals all had displayed broad smiles in roughly the same numbers (see Table 6).

Also, if facial dominance of cadets as measured here indicates an individual's conformity with the values of the hierarchy, then, in addition, we should expect a correlation with *GOM* in the predicted direction, which could not be observed (Table 1).

In addition, presentation of oneself as being in conformity with the values of the hierarchy is a feature that will be valued for all promotions. If facial dominance is valued as indicating a candidate's devotion to the values of the military hierarchy, then, by all that we know about socialization in professions and organizations, we should expect that facial dominance should also influence one's chances for promotion during early and middle career. Candidates have to provide portraits, which are included in the files open to inspection by

TABLE 5: Smiling in Portraits of Men by Cadet Ranks in Senior Year[a]

Cadet rank	No or Slight Smile	Broad Smile
Captain	30	10 (25%)
Lieutenant	84	28 (25%)
Sergeant	412	105 (20%)
All	526	142 (21%)
(N = 669)		

[a] Data from *Howitzer*

promotion boards for all ranks. Again, the most ambitious candidates should have provided more dominant portraits in order to advertise their adherence to the values of the hierarchy, and it should have worked. If, besides smile, official portraits leave a man only little room for varying his facial dominance, then, given the stability of facial dominance scores through the life course, we should expect a positive effect of facial appearance as rated from the graduation portraits, on promotions throughout the whole career, which could not be observed. But if an officer, anticipating the expectations of promotion boards, can substantially vary his facial appearance on official portraits, why should portraits in early and mid career, but not in late career, differ in this respect from the portraits taken at the academy?

Therefore we are left with the alternative interpretation: that facial dominance also in the context of the modern military measures what the raters were asked to assess: the capability to actually dominate other people, even if this ability in the social context must be applied only in a subtle and purely symbolic way.

There are many instances of contests, both intraspecific and interspecific ones, where it pays to fake. All other things being equal, an intruder often will defer to the owner of a territory who has already invested in it and for whom it is more valuable; a well-fed individual will defer to a hungry one. This should be beneficial to both sides, if such differences in intentions and interests are honestly signaled in order to avoid costly fighting. But there is the option to fake: pretend ownership or hunger. But then, why should an opponent believe such a signal?

When it comes to signaling relative contest abilities within a rank order, first Zahavi (1977), and in two rigorous papers Grafen (1990) and Enquist (1985) — see also Hasson (1994) — showed with game theoretical models that honesty can be an evolutionarily stable strategy: a strategy that in any real context will displace alternative strategies and cannot be displaced by them. There is only one condition for this finding to hold: the signaling itself must be costly and it

TABLE 6: Smiling in Portraits of Men by Future Final Rank (Lieutenant Colonel Rank and Above)[a]

Final rank	No or Slight Smile	Broad Smile
General	43	14 (25%)
Colonel	173	55 (24%)
Lieutenant colonel	112	27 (19%)
All	328	96 (23%)
(N = 424)		

[a] Data from *Howitzer* and *The Register*

must be more costly to signalers who actually are less able to fight. Several experimental observations are consistent with this prediction: for example, subdominant male house sparrows with experimentally enlarged badges (a signal of dominance) are attacked by birds with naturally large badges more frequently than other subdominant individuals (Møller 1987).

Among humans, signaling a contest ability that does not exist can also be punished very effectively. Many communities where rank is formally signaled by uniforms, titles, badges, etc., have strict punishment for fakers; there are equally harsh sanctions against individuals who informally signal a higher rank than they actually have.

In our sample, there are clear hints that signaling facial dominance without fulfilling the according expectations indeed was costly. Among men who did not graduate from war college and who had a GOM score in the poorer half (above 72), of all factors considered here facial dominance together with GOM was the most potent predictor for promotion to colonel, but — unlike GOM — a negative one ($R = -.13$, $p = .04$, $N = 76$); neither *athletic* nor *friends* had an effect in this particular subgroup. The higher the facial dominance score, the lower the chances for promotion to the highest rank obtainable for that subgroup (low grades at the academy; no war college), which in terms of professional performance was the weakest quarter of the whole sample. Some of these men, had they looked less dominant, might have risen higher than they actually did. Survival function differences in Table 3, while not approaching significance, accordingly speak more for a negative rather than a positive impact of facial dominance on chances of becoming colonel for nongraduates of war college in general.

Also, if we look only at final rank, while facial dominance scores rose from medium performers (colonel, no war college) over good performers (colonels who had graduated from war college) to top performers (generals), those men who did not graduate from a war college and were never promoted beyond lieutenant colonel looked almost as dominant as generals (see Figure 3).

It is interesting that, in this low-performing subgroup, year of promotion to lieutenant colonel highly correlated with facial dominance: the higher the facial dominance score, the later this last promotion had occurred (Spearman $r = .37$, $p = .001$). This was the only instance in this data set in which a strong significant relation could be observed between facial appearance score and a parameter of career timing.

We may conclude from these observations that if a man visibly failed to meet the expectations of his superiors and peers — that a West Point graduate excels in professional performance — and instead displayed only modest capabilities, then looking like a dominant military leader was a handicap rather than an asset. Parallels can be seen in that babyfaced individuals, who generally are perceived as warm, dependent and submissive, receive harsher punishment for wrongdoing (Berry & Zebrowitz-McArthur 1988; Zebrowitz, Kendall-Tackett & Fafell 1991). Furthermore, our finding is another strong piece of evidence against the "visibility" hypothesis: presenting oneself as conforming with the values of the hierarchy should never be a handicap.

Here we have the relative costs of overstating one's contest abilities that the theory requires for honest signaling as an evolutionarily stable strategy. Thus, facial dominance, as measured by the raters and perceived by the promotion boards, rather than being a symbol for something else, is perceived also in the context of a military career as honestly signaling individual contest capabilities; higher facial dominance scores indicating a greater probability to win in a contest against men with lower scores. In midcareer, at the ranks of lieutenant colonel and colonel, expertise, cognitive competence, and social intelligence are the required leadership qualities. On the top levels of the military hierarchy more archaic features of leadership matter, too. Selecting cadet officers at the academy also by the criterion *face* can be seen as a purposeful preparation for that dimension of leadership.

Is the military, with its warrior traditions, unique in its attention to dominant physical features? Perhaps, but there is reason to think that military promotion *understates* physical effects. Because of selective recruitment and socialization, West Point cadets look physically more impressive in face, physique, and posture than do students at other universities, and the same may be said of military officers compared to civilian professionals. Thus, there is less variation in appearance among military than among nonmilitary populations, and therefore less opportunity for physical selection into the highest status. Collins and Zebrowitz's (1995) finding — that babyfacedness, height and weight may have a greater impact on status attainment in civilian than in military settings — may be due to this sampling effect.

Furthermore, height, which is correlated with status in some civilian populations (Frieze, Olson & Good 1990; Gillis 1982; Hensley & Cooper 1987), was purposefully dissociated from rank at West Point, where in the 1940s cadets were assigned to companies according to their height, some companies consisting of tall men and others of short men, a practice since discontinued. Because promotions at West Point are purposefully distributed nearly equally across the cadet companies, the effect in those days was to distribute promotions across heights as well. Once the cadets graduated, height was no longer explicitly constrained from being a factor in promotion, but some implicit

constraint may have persisted since the height of classmen did not correlate with their ranks in later career either (Mazur, Mazur & Keating 1984). Considering all these factors, we believe that the effects of physical features on promotion are relatively understated in our military population. We predict that civilian institutions such as church hierarchies will show stronger physical effects on promotion.

If physical features are important determinants of socioeconomic status in the general population, then their incorporation into sociological models of status attainment would add considerable power. Methodologically this is feasible, since we have shown that photographs taken decades years apart can be scored with similar reliability for facial dominance. Trained interviewers could photograph respondents as part of the interview.

Since physical features are heritable, they may explain some persistence in status from one generation to the next. If one's parents attained high (or low) status partially through their looks, then by inheriting a similar look, one ought to be biased toward similar status attainment. Possibly controlling for looks would substantially lessen the traditional correlation between the social status of parents and their children. In our sample, however, military background of father had no impact on career chances (see the discussion of results) and, therefore, can be excluded as the underlying cause of the positive effect of facial dominance.

We believe it likely that there are interactions involving looks, race, and status attainment. For example, a dominant-looking black male in a white majority society might suffer inordinate suppression because he looks threatening, whereas a submissive-looking black man, by looking less intimidating, might be trusted more in business or school. For whites, who are not subject to fearful discrimination, dominant looks would facilitate upward mobility. Adding physical appearance to traditional models of status attainment would open wholly new possibilities for explanation.

Abstract

What are the locational processes that underlie racial residential segregation? This study analyzes the residential patterns of non-Hispanic whites, blacks, Hispanics, and Asians in eleven suburban regions using a multilevel model of locational attainment: the racial composition of a person's place of residence is determined by the person's individual characteristics (e.g., socioeconomic status and cultural assimilation) and aggregate variables including his or her racial/ethnic group, characteristics of the region in which he or she lives, and average characteristics of the group in that region. With some exceptions, findings for individual effects are more consistent with assimilation theory for Hispanics and Asians and with racial stratification theory for blacks. Having controlled for individual effects, disparities with whites are greatest for blacks, and for all three minority groups they are greatest in regions with large minority populations.

Residential segregation is one of the most enduring topics in the sociological literature on race and ethnicity (Massey & Denton 1993), but despite the decades-long effort devoted to its study, considerable uncertainty persists over the sources of observable levels of segregation. In part, this is because racial and ethnic residential segregation occurs in the context of a metropolis that is also segregated by social class and family life cycle (Shevky & Bell 1955). Since racial and ethnic groups typically differ in class and family characteristics, it is not obvious to what extent observed group differences in settlement patterns should be attributed to race and ethnicity and to what extent to other sources of segregation. In addition, sociologists have largely approached the study of segregation through the analysis of aggregate indices, such as the well-known index of dissimilarity (e.g., Lieberson 1963; Massey & Denton 1987). Problems of ecological inference have thus added to the difficulty of accurately assessing

* *A preliminary version of this article was presented at the 1992 annual meeting of the Population Association of America. the respective roles of the various personal and household characteristics that help to determine residential location. Our main purpose here is to estimate models at both the individual and aggregate levels (a form of multilevel analysis). This allows us (1) to disentangle the effects of race or ethnicity from associated characteristics such as socioeconomic status and life cycle, and (2) to distinguish between regional effects (that is, processes that affect all group members in a region) and individual effects (that is, processes that depend on a person's own attributes).

A Multilevel Approach to Racial and Ethnic Segregation

Early work by Duncan and Duncan (1955) and Taeuber and Taeuber (1965) established the utility of comparing measures of black-white segregation across metropolitan regions and over time. A handful of studies (such as Lieberson & Carter 1982; Logan & Schneider 1984; Van Valey, Roof & Wilcox 1977) reported segregation measures for city and suburban areas in the 1960-1980 period. These studies provided some indications of trends in segregation and the differences between the residential experiences of blacks and those of other minorities.

The field took a large step forward with the research program organized by Douglas Massey at Chicago in the 1980s (culminating in the recent publication of Massey & Denton 1993). Massey's group systematically combed census files for 1970 and 1980 to provide multiple measures of segregation (usually reporting on the index of dissimilarity and P* exposure measures) for blacks, Hispanics, and Asians, and for both the city and suburban portions of sixty metropolitan regions. Their essential strategy was to model differences in levels of segregation, estimating the degree to which segregation covaries with average characteristics (e.g., the median socioeconomic level) of group members.

Such analyses are inherently limited. To the extent that they are intended to examine true contextual effects (such as the effects of minority group size or housing market characteristics or age of the housing stock on segregation) — that is, effects that are presumed to affect all group members in the metropolitan region — their conclusions may be soundly based. But the step that one cannot take in a convincing way with segregation indices is to examine the individual determinants of location that produce the patterns of segregation observed at an aggregate level. As noted by Hauser (1974), apparent aggregate effects may mask any combination of individual and aggregate causal processes; inference from aggregate data to individual effects can be made without bias only where there are no real aggregate causal processes (Firebaugh 1978). This concern is also the basis for the multilevel models proposed by Mason, Wong, and Entwisle (1983).

The problematic nature of inferences about individuals from aggregate analyses is easily illustrated. A central question for research has been the effect of income on segregation, because it addresses the hypothesis that socioeconomic achievement of minority group members translates into spatial locations that more closely resemble those of the majority. Two analyses, both reported in Massey and Denton (1987) and both based on aggregate data, are especially

relevant to this hypothesis. In both cases, their analyses led to conclusions very different from those conducted for individuals.

In the first analysis, the dependent variable is the proportion of blacks (or Hispanics or Asians) living in the suburban area of the metropolitan region (taken as an indicator of breaking the spatial isolation of the inner city). The key predictor, income, is operationalized as the median family income of group members in the region. For no group is the coefficient for income significant at the .05 level. In contrast, Alba and Logan (1991) analyze the same question with an individual model (where the city versus suburban location of individuals is predicted by their own household income, among other variables). At the individual level, there are strong effects of income for all groups, though less strong for blacks than for other minorities.

In their second analysis, Massey and Denton predict the level of segregation of metropolitan regions. Segregation is indexed by the P* measure of "contact with Anglos," which is equivalent to the proportion that is non-Hispanic white in the place where the average minority group member lives. Again the median family income of group members in the region (tested in separate equations for blacks, Hispanics, and Asians) is included as a predictor. Surprisingly, a negative effect of income is found for Hispanics, with no significant effect for blacks or Asians. In sharp contrast, Alba and Logan (1993) report parallel analyses at the individual level for one suburban region (where the dependent variable is the proportion that is non-Hispanic white in the community where the person resides and the person's household income is included as a predictor). There are strong and significant positive effects for all three minority groups in New York suburbs.

If we interpret these apparently disparate results carefully, there is no contradiction between them. This is because sociologists are interested in two kinds of theoretical questions. Some questions call for comparisons among a group's experiences in different parts of the country (e.g., is the housing discrimination faced by a minority group's members less severe in regions where the group has a higher socioeconomic status?). Others clearly refer to processes that occur at the individual level (e.g., do more affluent members of a minority group in a given region have greater proximity to whites?). In principle, it could be true that *a person's* income has a strong positive effect on individual outcomes, but that the average income of *a group* has no independent effect.

On what empirical grounds can we reach conclusions about causal processes at each level? Our main point here is that cross-regional comparisons of segregation indices may be inappropriate at both levels. First, what is true of group averages may not be true for individuals: this is the point of the ecological fallacy. Second, even where the theoretical question is posed at the group level, cross-regional comparisons can be misleading if they do not control for individual processes. This is the point of much of the debate over contextual effects, where some have argued that what seemed to be contextual effects might disappear if individual effects were adequately controlled. Standard segregation indices include no such controls. But as we shall demonstrate, there is an alternative approach, in which segregation is studied first at the individual

level within regions and then measures of white-minority differences in location — measures that adjust for individual effects — are compared across regions.

Theories of Minority Residential Location

Before we describe our procedure, we can make the discussion more concrete by introducing the general theoretical models that are implicated in segregation research and their implications for hypotheses at both levels. The main theoretical debates can be organized around two broad approaches. From one influential perspective on race relations in the U.S., segregation mostly reflects group differences in resources and preferences. This perspective emerged out of the experience of European immigrant groups over the last century (Lieberson 1963; Lieberson & Waters 1988; Massey 1985). As minorities become assimilated into mainstream society, participating in American culture and advancing in education and class status, they are expected to move out of traditional enclaves and ghettos. Achievement, not ascription, is the key to opportunity, in the housing market as well as in factory and field. Massey (1985) has described this model with the term "spatial assimilation."

The persistent and high level of black-white segregation, by contrast, has supported a model of racial and residential stratification in American society. Observers have described a variety of mechanisms of public and private discrimination (see Farley & Allen 1987; Galster 1988). These mechanisms include both individual and institutional actions, ranging from acts of violence against the pioneer minorities in a community to restrictive zoning (Logan & Stearns 1981; Rieder 1985; Shlay & Rossi 1981). It has been argued that a dual housing market operates for blacks (and perhaps for other minorities). This means, for example, that realtors may show prospective white and minority home buyers houses in different neighborhoods and that financial institutions are more cautious in granting mortgages to minority buyers (for an extended discussion of discriminatory mechanisms, see Massey & Denton 1993). These generate racially segmented housing markets, which make it difficult for minorities to enter some communities and add to the cost they must pay for housing (Berry 1975; Foley 1973; Stearns & Logan 1986). From this perspective, racial inequality is an integral part of the social structure and is reflected in the unequal spatial distribution of groups. We refer to this as a place stratification model, because it is derived from a theory of how political processes impinge on community development (Logan 1978; Logan & Molotch 1987). The aggregate effects of the dual housing market are to reinforce inequalities between places. It might also be termed a racial stratification model.

These perspectives can be viewed as overlapping as much as they are competing. Where they are most clearly incompatible is in their assessment of black-white differences. From one side, the black case is viewed as exceptional (Massey & Denton 1993), or — for some observers, judging from the progress believed to have been made by the black middle class — perhaps in transition (Farley & Frey 1994). From the other side, it is the success of white ethnic groups that is considered exceptional, while emphasis is placed on the continuity of discrimination faced even by the most affluent blacks.

However, the application of these perspectives to the experiences of Asian and Hispanic groups is much less developed, despite the explosive growth of these minorities as a result of recent immigration. Thus, Asian and Hispanic groups offer new possibilities for testing aspects of the assimilation and stratification models. How are these new groups, some of whose members are relatively well educated and wealthy, being incorporated into American metropolitan areas? Is their settlement pattern consistent with their personal backgrounds, and can they achieve residential integration with the non-Hispanic white majority? Much research on these groups has examined their creation of ethnic economies (Wilson & Portes 1980; Zhou 1992). It has been argued that there is a high degree of voluntarism — and success — associated with the economic and residential boundaries that separate them from mainstream society (for the same argument applied to blacks, see Schelling 1971 and the recent investigation by Farley et al. 1994). What are the implications of such distinctive strategies for locational patterns of group members? Do assimilation and stratification models now have to be supplemented with an "enclave model" of residential incorporation? In particular, is there evidence that more affluent persons among these immigrant minorities are choosing not to live in "whiter" suburbs?

A number of hypotheses will direct our analysis. As noted, the spatial assimilation model indicates that the residential situation of minorities, including their degree of integration into the majority, changes with social mobility and assimilation. This notion leads to two broad hypotheses about individual effects:

Hypothesis 1. For the members of any minority group, residential integration with whites increases as their socioeconomic status increases.

Hypothesis 2. For the members of any minority group, residential integration increases with cultural assimilation.

Whites, regardless of their personal and household characteristics, generally reside in largely white communities. Nevertheless, socioeconomic status and assimilation should also affect the kind of suburb in which non-Hispanic whites live. As noted above, research with aggregate indices has yielded conflicting results on these hypotheses. Only a handful of studies have been conducted at the individual level. Gross and Massey (1991), Massey and Denton (1985), and Villemez (1980) found positive effects of socioeconomic status for whites, blacks, and (in the two later studies) Hispanics on the proportion of the population that was white in census tracts. Alba and Logan (1993) found positive effects of socioeconomic status for whites, blacks, Hispanics, and Asians for suburbs in the New York region. Assimilation measures, however, such as nativity and language, had no effect for Asians, negative effects for blacks, small positive effects for whites, and strong positive effects for Hispanics.

Researchers in both the assimilation and stratification traditions agree that African Americans suffer the most extreme segregation and also that this segregation is not explained by income differences between the white and black groups (Farley & Allen 1987). Hypothesis 3 extends this finding to a broader set of relevant characteristics.

Hypothesis 3. At no level of socioeconomic and assimilation status do African Americans achieve residential integration with whites on a par with other minorities (or whites). In operational terms, the predicted percentage of non-Hispanic whites in the community of residence of African Americans (taking into account relevant personal characteristics) is lower than in communities of similar members of other groups, majority and minority.

Research at both the aggregate level (e.g., Massey & Denton 1987) and the individual level (Alba & Logan 1993; Gross & Massey 1991; Massey & Denton 1985; Villemez 1980) reveals two relevant results. First, net differences between blacks and other groups remain after controlling for other variables. Second, the coefficients linking socioeconomic status to locational outcomes are typically lower for blacks than for other groups.

Predictions for other minorities are more ambiguous. From the perspective of the stratification model, these groups are distinctive minorities whom whites frequently attempt to exclude from their communities, though less systematically than is true of African Americans. From the perspective of the assimilation model, Asians and Hispanics can be seen as immigrant groups (Puerto Ricans excepted) subject to the processes of assimilation. Therefore they should achieve residential parity with whites once they attain favorable socioeconomic and assimilation characteristics. This is the finding of Alba and Logan (1993) for the New York suburbs, supporting hypothesis 4:

Hypothesis 4. At higher levels of socioeconomic and assimilation status, Asians and Hispanics are residentially integrated with whites to the same degree as whites with similar characteristics.

Hypotheses 1-4 are stated for individuals and must be tested with individual-level models. Other hypotheses deal specifically with effects that can be tested only through interregional comparisons. We begin with the aggregate or context-level counterpart of hypotheses 1 and 2. Irrespective of a person's own attributes, processes of segregation may be ameliorated for a group as a whole insofar as it resembles the majority population in its socioeconomic or assimilation characteristics.

Hypothesis 5: The segregation of a minority is reduced where its average socioeconomic or assimilation status is higher.

Fundamental to the place-stratification model is the notion that whites seek to avoid residence with certain minorities. It is plausible that this avoidance would be more pronounced where these minorities are large in number (and, inversely, that whites would be less likely to erect residential barriers against small numbers of minority-group residents). In addition, where large numbers of a minority group are present, they may form their own residential enclaves. This reasoning leads to a region-level hypothesis concerning minority-group size, similar to the suppositions of other researchers (e.g., Blalock 1967; Massey 1985; Stearns & Logan 1986):

Hypothesis 6. Because whites tend to segregate themselves from large concentrations of minorities and because large groups may form their own suburban residential enclaves, the degree of segregation of a minority group should vary with its size. The effect should

be largest for African Africans, because white attempts to preserve distance from them are most systematic.

One common measure of segregation, the P* index of exposure between groups, depends inherently on group size. All else equal, a larger minority group has a lower exposure to whites, but the exposure of whites to the minority group is higher. We must be careful, therefore, to operationalize segregation in a way that avoids such bias.

Finally, racial/ethnic stratification across communities is part of a more complex system of stratification among communities, in which social class also plays a salient role. We expect that where communities are more stratified in general, there is more opportunity for racial/ethnic stratification by place. Therefore we hypothesize

Hypothesis 7. In regions where communities are more highly stratified (reflected in greater income disparity between suburbs and the central city, or among suburbs themselves), the segregation of racial/ethnic minorities tends also to be greater. This effect should be most pronounced for African Americans.

Research Design

In this article, we address these hypotheses through an investigation of minority residential integration with whites in suburbia, developed from a comparison of four major racial ethnic groups (non-Hispanic whites, non-Hispanic blacks, Hispanics, and Asians) in the eleven largest metropolitan areas in the nation in 1980. We employ a multilevel research approach. Assimilating and segregating processes *within* metropolitan regions are modeled at the individual level, including all relevant characteristics of minority-group members that may affect their access to communities with higher proportions of majority-group residents. Comparisons *across* regions, then, are based on segregation measures in which these individual processes have been controlled.

Such an approach is now possible, using readily available census data sets and by applying a methodology developed by Alba and Logan (1992-93; see also Alba, Logan & Bellair 1994 for a step-by-step review of the procedures). This method employs a model with the following form:

$$Y_{ij} = a + b_1X_{1ij} + b_2X_{2ij} + b_3X_{3ij} + \epsilon_{ij} \tag{1}$$

where Y_{ij} is a community-level measure for community *j* and thus is assumed to be constant for all individuals *i* in the same *j*; and the *X* variables are individual and household-level variables that predict residence in a community with a given level of the trait measured by the dependent variable. In the present case, Y_{ij} is a measure of community racial composition — specifically, the percentage of non-Hispanic whites among residents — which links it directly to a well-known measure of segregation, P* (Lieberson & Carter 1982; see Alba & Logan 1993 for a discussion of this linkage). The *X* variables cluster into certain types: X_{1ij} is the household income or another human-capital variable for individual or household *i* in community *j*, X_{2ij} is English-language ability or another assimilation measure, and X_{3ij} represents other (possibly

control) variables, such as household configuration or age. The model is estimated for the individual or the household as the unit and separately by racial or ethnic group.

Such a model can be interpreted in the same fashion as other status-attainment models (Blau & Duncan 1967). Each *b* coefficient establishes the degree of conversion of a minority individual's or household's characteristics, such as income, into a residential setting of low segregation (i.e., a community with many whites or, alternatively, nongroup members). Estimating effects of this sort has been a rather consistent goal of research on residential processes, but in the past it has been attainable only with specially constructed data sets or by an indirect route, using aggregate-level equations and thus risking the ecological fallacy (see, e.g., Massey, Condran & Denton 1987; Massey & Denton 1985; Villemez 1980; White, Biddlecom & Guo 1993).

To solve the problem of estimating locational attainment models at the individual level, we construct appropriate correlation (or covariance) matrices by combining correlations (or covariances) from two different kinds of U.S. census data sets. From the tabulations in Summary Tape Files (especially Summary Tape File 4B, which provides a wide variety of tables separately by racial or ethnic group), we estimate the correlations between the aggregate dependent variable and individual independent variables (these are the *XY* correlations). From Public Use Microdata Samples (PUMS), we estimate the correlations among the independent variables (the *XX* correlations). Ordinary least squares (OLS) regression equations are then estimated directly from the correlation matrices (along with means and standard deviations) prepared from these sources.

It may be easier to understand this procedure by imagining that we had begun with PUMS data to which somebody had appended the white percentage of each person's community of residence. Then we would have directly calculated the correlation between each individual characteristic and white percentage (the *XY* component of the matrix) and the correlations among predictors (the *XX* component of the matrix) from the same convenient data file. These would be exactly the same correlations, based on the same census sample data, as the ones that we calculate. Our method introduces no new conceptual complication.

Data and Variables

We study the suburban portions of the 11 largest metropolitan regions of the U.S. in 1980. When this analysis was completed in early 1995, the Bureau of the Census had only begun to release the group-specific Summary Tape Files from the 1990 census. Availability of those files will make it possible to test for changes in the patterns reported here. In order to avoid the sometimes arbitrary separations between neighboring primary metropolitan areas (e.g., between the New York PMSA and the Nassau-Suffolk PMSA), we have defined these metropolitan regions in the broadest possible fashion in each case, using the 1989 Consolidated Metropolitan Statistical Area (CMSA) boundaries.

The metropolitan areas in the analysis are displayed in Table 1, which also shows their constituent primary metropolitan areas and other data. The

suburban portions of these areas (1980 figures) encompass approximately 3.5 million Hispanics, 2.8 million non-Hispanic blacks, and 1.0 million Asians (along with 35.4 million non-Hispanic whites). The regions vary greatly in their minority presence, from Boston (whose suburbs are about 3.1% minority) to Los Angeles (where minorities comprise nearly 35% of the suburban population). They also vary in the predominant minority group. Hispanics are the largest minority in Los Angeles, Miami, San Francisco, Dallas, and Houston. Blacks are most highly represented in Washington and Miami. Asians are above 2% of the suburban population only in San Francisco, Los Angeles, and Washington.

Data suppression by the census, which does not report group-specific figures for places with few group members, reduces the number of places included in the following analyses. However, on average across the 11 metropolitan regions in this study, the included places encompass between 98% and 99% of non-Hispanic whites, non-Hispanic blacks, and Hispanics. The coverage of Asians averages 95%, ranging from 88% in Boston to 100% in Houston and Miami. The main effect of suppression is probably to understate the residential integration of suburban Asians, whom we will nevertheless show to be highly integrated with whites.

For some purposes, such as reflecting the sources of segregation between central city and suburban areas, analyses should include the entire metropolitan area. There are both theoretical and practical reasons for studying only suburban areas here (for analysis of city/suburb differences, see Alba & Logan 1991, Massey & Denton 1988, Stearns & Logan 1986). As Farley and Frey (1994:25) argue, the creation of segregated suburbs has been the key to persistence of segregation in the postwar era. Implicitly the opening of suburbs might be the key to its breakdown (see especially Frey & Speare 1988:240-41). For this reason, the suburban ring has drawn special attention from sociologists (Logan & Schneider 1984, Massey & Denton 1988, Stearns & Logan 1986).

Suburban communities are particularly relevant to the place stratification model. This model envisions communities as collective actors that employ a variety of strategies to protect or enhance their position in a hierarchy of places. Such communities are far more naturally operationalized as "places" in U.S. Census terminology than are the more familiar census tracts. For the most part, places in the census tabulations represent communities incorporated as villages, towns, or cities, although the Census Bureau also accepts as places locally recognized communities that have no separate legal existence. In such a scheme, however, it makes little sense to include central cities as places, given the different order of magnitude of their size. Finally, although analyses based on census tracts or block groups would reveal additional segregation *within* suburbs, the overall racial composition has significance in its own right, as expressed in such factors as the community's reputation and the composition of its school population.

In 1980 census data, there is an additional, practical reason to prefer places to tracts: namely, place-level tabulations for racial/ethnic groups (in Summary Tape File 4B) are based on more precise group definitions than their tract-level equivalents (in Summary Tape File 4A). In particular, separate tabulations for non-Hispanic whites and non-Hispanic blacks are available for places but not for tracts. At the tract level, tabulations for whites and blacks include Hispanics

TABLE 1: Metropolitan Area Definitions and Racial/Ethnic Composition of 1980 Suburban Population

CMSA *PMSA*	Percent White	Percent Black	Percent Hisp.	Percent Asian
Boston *Boston, Brockton, Lawrence-Haverhill, Lowell, Nashua, Salem-Gloucester* (339 places, mean population 12,789)	96.9	1.1	1.2	0.7
Chicago *Aurora-Elgin, Chicago, Gary-Hammond, Joliet, Lake County, Ill.* (457 places, mean population 9,811)	89.3	5.1	3.7	1.7
Dallas *Dallas, Fort Worth-Arlington* (208 places, mean population 7,890)	89.7	3.8	5.4	1.0
Detroit *Ann Arbor, Detroit* (272 places, mean population 12,652)	93.5	4.3	1.2	0.8
Houston *Brazoria, Galveston-Texas City, Houston* (150 places, mean population 9,352)	80.9	6.8	10.7	1.4
Los Angeles *Anaheim-Santa Ana, Los Angeles-Long Beach Oxnard-Ventura, Riverside-San Bernardino* (303 places, mean population 23,020)	65.8	6.5	23.0	4.5

and thus overlap with tabulations for the Hispanic group. Therefore our analyses are restricted to suburban communities only.[1] We have nevertheless replicated these analyses for census tracts in the New York metropolitan region, and in that case the pattern of group differences is very similar to the one reported here (Logan et al. 1992).

Locational attainment models are estimated separately for each of four major racial/ethnic populations: non-Hispanic whites, non-Hispanic blacks, Hispanics, and Asians. Recognizing the potential importance of racial/ethnic differentiation within these groups, we include in each model (aside from that for non-Hispanic blacks) a series of dummy variables to represent subgroups. The model for whites has dummy variables for six major categories of single ancestry: English, French, German, Irish, Italian, and Polish; the omitted category contains individuals with any other single ancestry or with mixed ancestry. The model for Asians distinguishes among the following groups: Asian Indian, Chinese, Filipino, Japanese, Korean, and Vietnamese; the omitted category contains all other Asians. Finally, the model for Hispanics contains two sets of dummy variables. One set distinguishes among various nationality groups — Cubans, Mexicans, Puerto Ricans, and other Hispanics (omitted category) — and the other set among different racial groupings — white, black, and other (omitted category).

Other characteristics of individuals in our models are also represented in dummy variable format. This representation reflects the categorical presentation of variables in census tabulations. A side benefit is that this choice creates an intuitively compelling interpretation for the intercept, usually a largely forgotten parameter in regression interpretation, which takes on the predicted value for the percentage of non-Hispanic whites in the community of residence of an individual who is in the omitted categories of all the independent variables. The other independent variables in our models follow.

INDIVIDUAL ASSIMILATION

The measures of individual assimilation included are English-language ability (in the categories those who speak only English at home, who speak English well, and who do not speak English well), along with nativity and immigration status (categories: U.S. born, arrived before 1975, and arrived 1975 or later). The omitted categories are the first named in each case. Puerto Ricans, as U.S. citizens, are coded as U.S. born. As stated in hypothesis 2, the spatial assimilation model would anticipate less desirable spatial outcomes, and thus less residential integration with non-Hispanic whites, for recent immigrants, and more desirable locations for those who speak English well.

INDIVIDUAL SOCIOECONOMIC STATUS

Socioeconomic variables are home ownership (2 categories, with renter the omitted category), household income (9 categories, from under $5,000 to $75,000 and above, with the lowest category omitted), and education (5 categories, from grammar school to college graduate, with the lowest omitted). As formulated in hypothesis 1, a central tenet of spatial assimilation theory is that, controlling for

other relevant characteristics, minority-group members who have achieved higher socioeconomic standing will gain access to desirable locations equal to those of majority-group members of the same status. The theory implies a positive effect of socioeconomic variables on proximity to the majority.

DEMOGRAPHIC COMPOSITION

The demographic variables include age and household composition. Age is divided into five categories: individuals younger than 5, age 6 to 17, age 18 to 24, and 65 and older, with those of prime working age (25-64) forming the omitted category. Household composition is divided into four categories: married-couple households, other family types, nonfamily households, and institutional settings, with nonfamily households the omitted category. Both variables are included as necessary controls, because they have previously been shown to be independently associated with community characteristics and with suburban residence. Their effects are widely understood to indicate a preference, or greater willingness, to invest in location for married couples with children. These variables are also implicated in the construction of others, necessitating their explicit appearance in the models.[2]

The foregoing are the individual-level variables in locational attainment models that are separately estimated by group and metropolitan region. The *dependent variable* for these models is the percentage of non-Hispanic whites in the community (place) of residence.

As stipulated in hypotheses 5-7, our analysis also extends to intermetropolitan comparisons, in which individual processes have been controlled. The dependent variable at the regional level is the difference between the proportion that is white as predicted for a *minority group's members* and the proportion that is white as predicted for *whites* who have the same socioeconomic and assimilation characteristics.[3] Predictors, following previous cross-regional studies of segregation, are average characteristics of the minority in the region and characteristics of the region itself. We investigate group size, group composition, and suburban stratification.

GROUP SIZE

The minority versus white disparity is expected to be correlated with the proportions a group composes of the metropolitan region and of its suburban portion. According to hypothesis 6, these correlations should be positive.

GROUP COMPOSITION

These variables reflect the average characteristics of a group's suburban residents in the region: the percentage who have median household incomes of $40,000 and higher; the percentage who are college educated; the percentage who are U.S. born; the percentage who speak only English at home.

SUBURBAN STRATIFICATION

Suburban stratification in a metropolitan region is measured by the income disparity between suburban and central-city household incomes (index of net difference) and the income differences between places within suburbia (the standard deviation of median household incomes). Note that these measures tap different aspects of stratification: the index of net difference measures the overall socioeconomic selectivity of a region's suburbs, while the standard deviation measures the inequalities between suburban places. According to hypothesis 7, segregation can be expected to be greater where income stratification is greater.

Results

PREDICTING INDIVIDUAL EFFECTS

The first task is to understand how members of different racial/ethnic groups are channeled into communities of various compositions according to their personal and household characteristics. Table 2 summarizes the prediction equations for the four racial/ethnic groups in all 11 metropolitan regions. Because of space constraints the table lists only six parameters from these equations; complete regression equations are available from the authors on request (for the New York equation, see Alba & Logan 1993). Many of the omitted coefficients (such as those for various categories of income) are statistically significant but are redundant because the effect of the variable as a whole is reflected in the coefficient for its most extreme category. Nonsignificant coefficients are omitted. "Owner" is the coefficient for home ownership (as opposed to renting). "High Income" is the coefficient for persons with household incomes of $75,000 and above. "College" compares persons with college education to those with less than high school. "No English" compares those who do not speak English well with people who speak only English at home. Finally, "New Migrant" compares a post-1974 immigrant to native-born persons.

The intercepts are adjusted in two ways. First, they represent the typical case of persons in married-couple families (i.e., we have added the coefficient for married-couple families to the estimated intercept). Second, they represent the region's unique distribution of group members among national origins. As noted above, national origin categories for whites, Hispanics, and Asians are included in the equations, though they are not listed in Table 2. Predicted values from the equations depend, for example, on whether we assume that a Hispanic person is Mexican, Cuban, Puerto Rican, or "other." It would be unreasonable to assume the same category for every region (for New York, a Puerto Rican is most typical, but this is not true for Miami or Los Angeles). Therefore we have adjusted the intercepts to reflect what is "typical" for each region (adding a weighted average of the national origin coefficients, based on the number of persons of each origin in the region).

We begin by noting that the explained variance in these equations tends to be low, especially for whites. Of course one would not expect explained variance to be in the high range found in ecological studies, which ignore the

internal heterogeneity of communities. (Remember that the individual is the unit of analysis here. The number of cases depends on population size rather than the number of suburban places; in each region it is the number of cases reported in PUMS, with an arbitrary maximum of 10,000.) But the low range of R^2 for whites from .02 in Philadelphia to .07 in Boston also reflects the uniformity in white settlement patterns: most whites live in largely white communities regardless of their personal attributes of age, income, ethnicity, etc. In several suburban regions, the explained variance for blacks and Asians is comparable to that for whites, although it is higher in other regions. (The range for blacks

is from .03 in Washington to .16 in Boston, while for Asians it goes from .04 in Los Angeles to .23 in Boston.) In contrast, we find that background characteristics have their strongest effects on Hispanic settlement. The explained variance ranges from .06 (Houston) to .45 (Philadelphia). Hispanics tend to have greater heterogeneity in background characteristics than either blacks or Asians, to live in a greater variety of suburbs, and to have stronger relationships between their own background characteristics and the racial composition of their place of residence.

Let us consider now the regression coefficients themselves. According to hypothesis 1, income, education, and home ownership are expected to have positive effects on residence in suburbs with higher white proportions. Our results consistently support this expectation for whites. Out of 33 coefficients in the white equations (one for income, one for education, and one for home ownership in every region), 26 are statistically significant and positive. For Hispanics, most coefficients for income and education are significant and positive (18 of 22), but there are several cases where the home ownership coefficient is either not significant (4 cases) or is actually negative (3 cases). The exceptions for Asians include 4 cases each in which income, education, or home ownership is not significant. Finally, for blacks there are 4 cases each in which income or education is not significant and 9 cases in which the home ownership effect is negative.

These exceptions should not be overemphasized. Either higher income or higher education is associated with living in "whiter" suburbs for all three minority groups in almost every metropolitan region. Boston is an exception for minorities as well as for whites. Washington and Houston are exceptions for blacks; Miami and Dallas are exceptions for Asians. Members of minority groups with household incomes of more than $75,000 and/or college education typically live in suburbs with 5% or even 10% more white residents, in contrast to the poorest or least educated minority group members. And in most cases, the combined effects of these two indicators are greater for minorities than for whites. (This reflects our statement in the theoretical section of this article that most whites live in suburbs with high proportions of white residents, regardless of their personal background.)

But the results for home ownership point in a different direction. According to the assimilation model the additional resources represented by home ownership should increase choice about where one lives. For whites, in fact, there is typically a small positive effect of home ownership, so that white homeowners live in suburbs whose white percentage is 1 or 2 percentage points above what is predicted for white renters. There are two exceptions, Philadelphia and Los Angeles, while the largest effect is found in New York (5.8 points). By contrast, home ownership in most cases has a negative effect for blacks. Thus, in virtually all the regions (Boston is the one exception), black homeowners are further behind comparable whites than are black renters. Ownership does not behave as just another indicator of socioeconomic status. We suggest that the reason may lie in the dual-housing markets posited by the stratification model. If the market for home purchase by blacks were more geographically restricted than the market for rentals, then black owners would be more likely to reside in black neighborhoods. Indeed there is support elsewhere in the

literature for this interpretation: Stearns and Logan (1986) found that black suburbanization is greater in regions with a higher proportion of rental housing, and black-white segregation is lower in such regions.

The effects of home ownership are not as clear-cut for Asians and Hispanics. In some cases, the effects are positive, although only in New York could they be called substantial. In a few cases, they are negative, but mostly small. The largest negative effect is found for Hispanics in Philadelphia (-5.5). Thus, neither the assimilation nor the stratification model seems to fit the effect of ownership among Asians and Hispanics. Perhaps there are countervailing effects, leading to no net impact. Or perhaps whether home ownership is an asset or a liability for residential integration with the majority depends on other characteristics of the region (presumably aspects of the regional housing market) that we cannot identify here.

The next pair of variables — language and nativity — serve as indicators of cultural assimilation, which is central to the broader assimilation model as applied to immigrants (reflected in hypothesis 2). Among whites, there is only one case where immigration status affects residence: Boston, where recent immigrants are predicted to live in suburbs with 2.2% fewer white residents. There are more cases where poor English language ability affects whites, yielding about a 5-point difference in Los Angeles, Miami, and New York. The small number of significant effects suggests that white ethnicity, as reflected in recent immigration or poor English, does not have much éffect on the racial composition of suburbs where whites settle. Not surprisingly, English language ability proves to be irrelevant for blacks, whose native language (even for immigrants) is normally English. In seven cases, however, immigration is significant and — quite the contrary to expectations from assimilation models — positive. In the suburbs of Chicago, Los Angeles, and Miami, black immigrants live in suburbs with a white concentration as much as 15 percentage points higher. It should be noted that immigration status is paralleled by an ethnic distinction among non-Hispanic blacks, for West Indians (including Haitians) comprise the majority of the foreign born and often strive to preserve some distance from native-born African Americans (Kasinitz 1992).

Among the major recent immigrant groups, Hispanics and Asians, we find two opposite patterns. Hispanics, in ten of the eleven regions, are likely to live in less-white suburbs if their English is poor. For Asians, there are only two regions, San Francisco and Los Angeles, both of which have large and long-standing Asian settlements, where limited English language ability reduces Asian integration with whites. In most cases, immigration status is also nonsignificant. Thus cultural assimilation usually seems to be irrelevant to suburban Asians' residential patterns.

The results from Table 2 can be summarized as follows. First, as anticipated from the assimilation model, persons of higher income or education in most regions live in suburbs with higher proportions of white residents. Advancing socioeconomic status promotes suburban racial integration for blacks, Hispanics, and Asians (although higher socioeconomic status for whites simultaneously abets white exclusivity). Home ownership must be distinguished from other socioeconomic indicators because of the effects of dual-housing markets. Ownership is not typically associated with substantially greater minority

exposure to whites. And for blacks, in particular, ownership is most often linked to living in suburbs with more minority residents. Finally, assimilation as reflected in language ability is sometimes associated with living in whiter suburbs for whites, and in nearly every case for Hispanics. But neither assimilation variable is significant for Asians, and recent black immigrants actually have an advantage over native-born blacks.

THE NET EFFECTS OF INDIVIDUAL PROCESSES

The regression models summarized in Table 2 focus on the individual processes that lead some group members to have greater exposure to whites than do others. We have to this point avoided the issue of how the net results of these processes for racial/ethnic integration vary across the metropolitan regions. For this we need, for each group and each metropolitan area, a summary measure of residential integration with whites, net of the personal and household characteristics of individual minority-group members. We use several measures that reflect the difference between the percentage of non-Hispanic whites where a white lives (or is predicted to live) and the percentage of non-Hispanic whites where a minority person lives. A larger value means a greater disparity; the few negative values are cases where the minority group member is actually predicted to live in a whiter community than is the corresponding white.

One measure is based on the *unadjusted* percentage of whites in the community in which the average group member lives (this is, in fact, the difference in traditionally calculated P* for exposure to whites as calculated for whites and for each other group). We also present four indices that adjust for individual characteristics. The difference between the *predicted value* for whites and members of each minority group is a measure of the extent to which minority group members are residentially segregated even after adjusting for compositional differences. A group is more subject to segregating processes in a given region, we would say, when there is a greater discrepancy between the kind of suburb where group members and the kind where *comparable* whites live. This discrepancy depends on the coefficients of the locational attainment equations and on whatever combination of personal characteristics is assumed. We calculate indices for four combinations. The first is for individuals whom we describe as "poor immigrants": persons aged 25-65, in married-couple family households, renters, with incomes less than $5,000, who attended grammar school only, do not speak English well, and immigrated after 1974. A second is for "poor natives": the settings are the same as for the previous case, except that these individuals are native-born and speak only English at home (these correspond to the intercepts from Table 2). The third and fourth vary the socioeconomic variables. "Average" natives have the average characteristics of non-Hispanic whites across these eleven regions: they are homeowners and high school graduates with income of $20,000-29,999. Finally, "affluent natives" are homeowners with incomes of $75,000 or more who have completed college.

The Appendix table lists these values separately for all eleven metropolitan regions. For simplicity, we focus on the averages across regions presented in Table 3. Without introducing any adjustments for personal background (the first row of Table 3), we find that the average black lives in a suburb that has a

white percentage more than 25 points below the suburb of the average white. The average Hispanic is considerably more residentially integrated with whites, with a gap only half that magnitude. And this gap is even smaller for the average Asian. These figures confirm previously reported group differences in segregation in suburbia.

Now consider the impact of controlling for people's background characteristics other than race or ethnicity. The results vary across groups. Among Asians, these controls have much less impact on where they live than on where comparable whites live. This is because Asians differ from whites primarily in the proportion of immigrants among them, but we have seen that immigrant Asians in most suburban regions are about as residentially integrated with whites as are U.S.-born Asians or as those who speak only English at home. Asians have socioeconomic characteristics similar to those of whites, and in most regions the combined effect of socioeconomic variables is similar for Asians and whites, so controlling for this important predictor has little effect on white-Asian residential disparities. Some exceptions are found in the Appendix table. In New York-New Jersey and Washington, D.C., for example, the Asian disparity from whites declines clearly with socioeconomic advancement. But in most regions such a pattern is either small or nonexistent.

Among Hispanics, in contrast, the effects of introducing individual control variables are substantial and in the direction anticipated by assimilation theory. The category of Hispanics with the largest disparity with comparable whites is poor immigrants, because the cultural assimilation variables (language, nativity) have powerful effects on Hispanic residential location (much stronger than they do on whites). On average, there is almost no difference in predicted white percentage for affluent native Hispanics and affluent native whites. (We refer to white Hispanics; the dummy variables for race in the Hispanic equations, not included in Table 2, reveal that black Hispanics live in suburbs that are about 10% less white than do white Hispanics.) The pattern in which both cultural assimilation and socioeconomic advancement reduce Hispanic-white disparities is almost uniform across regions. One of the clearest cases is New York-New Jersey, where poor immigrant Hispanics live in suburbs of quite different racial composition than do poor immigrant whites (a 26.6 point disparity, greater than the mean difference between groups before introducing control variables). But for poor natives, the gap is cut nearly in half, and at the highest levels of income and education the difference actually favors Hispanics.

Finally we consider the black case. For the category of people that we identify as "poor immigrants," the difference from whites with the same backgrounds is much reduced among blacks (from 26.7 down to 10.8). For the equally poor category of natives, the disparity with comparable whites is much larger (23.1 percentage points). This reflects the fact that black immigrants are more residentially integrated than are native blacks. The socioeconomic variables also operate in a unique way for blacks. "Average native" blacks have a greater disparity with comparable whites than do "poor natives." This is because the "average" socioeconomic category includes home ownership, which we found to have negative effects on residential integration of blacks. The home ownership effect outweighs the positive income/education effect. Only at the

TABLE 3: Average Difference in Predicted Racial Composition (Percent Non-Hispanic White) between Whites and Minority Group Members with Various Combinations of Personal Characteristics

	Non-Hispanic Blacks	Hispanics	Asians
Not adjusted[a]	26.7	13.3	5.0
Poor immigrant	10.8	14.3	4.0
Poor native	23.1	9.1	5.7

Affluent native	17.8	1.7	2.4

[a] Equivalent to the difference in P* (exposure to non-Hispanic whites) for whites and minority group members

highest levels of income and education do these aspects of socioeconomic standing counterbalance home ownership.

This sort of examination of Table 3 bears directly on hypotheses 3 and 4, which predict that Asian and nonblack Hispanic integration will resemble that of whites themselves at higher levels of socioeconomic status and assimilation, but that African Americans will lag behind. Only for the unusual case of immigrant blacks are black-white disparities comparable to disparities measured for Hispanics or Asians. And for nonimmigrants, even a college degree and income over $75,000 do not result in black parity with whites. For this category, the disparity for blacks in 17.8 points, while near parity is found across these eleven regions for Hispanics (1.7) and Asians (2.4).

INTERPRETING REGIONAL VARIATION

Finally, we address regional variation in segregation. Previous studies have treated unadjusted measures of segregation (the index of dissimilarity or exposure index) as the dependent variable to be explained by other regional characteristics. The new measures introduced in Table 3 and the Appendix have the advantage of having controlled for individual processes. Again we simplify the presentation, using only the "average native" values. These are the most relevant, we believe, because they reflect situations in which all people are assumed to have the characteristics typical of the white population.

Table 4 reports the correlations of these indices with various characteristics of regions and of groups within regions. Our first region-level hypothesis (hypothesis 5) concerns the ameliorating impact of the average characteristics of group members: where the average status of a group's members is high, the predisposition of the majority to exclude them (or of the minority to segregate itself) may be lower. The correlations in Table 4 offer mixed support for this proposition for Hispanics and Asians, but show that segregation for blacks is

not affected by their average status. In the case of Hispanics, the percentage who are native born and the percentage who speak English at home are negatively correlated with net segregation from whites (-.64 for both variables). For Asians, the percentage who are college educated is also negatively correlated with segregation (-.76), but the correlation with Asian median income is smaller and not significant.

Another expectation is that a minority's size should affect the degree of its segregation from whites (hypothesis 6). We tested first for the size of each minority group. The correlations are around .80 for Hispanics both for the proportion the group comprises of the CMSA's overall population and also for its share of the suburban population. The positive direction is the one implied by hypothesis 6, for it indicates that the difference in residential pattern between whites and a minority grows as the size of the minority increases. The correlations are smaller for blacks and Asians. We also calculated correlations for the size of all three minorities added together — perhaps segregating processes depend not so much on the size of any one group as on the presence of minorities altogether. These coefficients are significant for all three groups (.56 for blacks, .80 for Hispanics, and .86 for Asians).

There is also some indirect evidence that size affects Hispanic segregation. In the regressions summarized in Table 2, we included dummy variables to represent subgroups (these are not reported in the table). In the Hispanic equations for seven regions, being Mexican is associated with less exposure to whites, and these include the regions in Texas and California where Mexicans are highly concentrated. In two cases the Mexican coefficient is positive; these are New York and Miami, where Mexicans are a small portion of the Hispanic population. There is a similar pattern for Puerto Ricans, with six cases of negative effects including New York; the only positive coefficient is for Houston, with few Puerto Ricans. Finally, Cubans are found to live in less white suburbs in four regions, including Miami; the only positive Cuban coefficient is in San Francisco. It appears, then, that the subgroup that constitutes the local Hispanic majority tends to be most segregated from whites in suburban regions.[4]

Suburban income stratification is also expected to be related to racial/ethnic segregation (hypothesis 7), because class-based exclusion may be a means for affluent whites to restrict the number of suburbanizing minorities in their communities. Table 4 includes two measures of income stratification, and the results are contrary to the hypothesis. Only one variable has significant correlations, and these are in an unexpected direction (the city/suburb index of net difference is negatively correlated with Hispanic and Asian disparities with whites). These results suggest that the extent of class segregation between city and suburbs or among suburbs is not an indicator of processes of racial exclusion.

Given the small number of regions involved in this analysis, it would be inappropriate to extend the correlations to a full-fledged multivariate analysis. By applying the analysis to 11 regional cases for each social group, however, we can offer a more parsimonious test of the results (yielding 33 cases for analysis). Our procedure was to conduct a stepwise regression in which dummy variables are entered first to represent the Hispanic and Asian minorities (blacks are the

TABLE 4: Correlations between the Discrepancy in Predicted Values[a] of Suburban Racial Composition for Whites and Minority Group Members and Various Characteristics of the Groups and Regions

[a] Predicted values are for persons with these median or modal characteristics: age 25-64, married couple household, native born, speaks only English, homeowner, income $20,000-29,999 and high school graduate.

* $p < .05$ (two-tailed test)

omitted category). Then we test separately the significance of each variable from Table 4. Finally, for every such significant variable, we test its interaction effects with the race variables.

These procedures lead to a final simple model:

$$(1)\ \textit{Disparity} = 17.23 - 21.65\textit{Asian} - 13.42\textit{Hispanic} + .55\%\textit{Minority}$$
$$(\textit{Adjusted}\,R^2 = .654)$$

We find significant effects of race. The only variables that add significantly to race are those representing group size in the suburbs, and of these the strongest effect is for the combined size of all three groups. No interactions with race are significant. According to the coefficients, the disparities between whites and both Asians and Hispanics are substantially smaller than disparities with blacks, even after all individual sources of variation in residential placement are controlled. And net segregation for all groups is greater in suburban regions

where minorities comprise a larger share (and consequently, whites comprise a smaller share) of the population.

The relationships summarized in this equation can also be illustrated in a scatter diagram. Figure 1 shows how the difference between white and minority values (differences in the predicted white percentage in the suburb in which an "average native" person lives) is associated with the total minority proportion (black, Hispanic, and Asian) in a region. Every point represents a region. Points shown as small boxes represent white-black disparities. It is clear from Figure 1 that these are in every case higher than white-Asian or white-Hispanic disparities (both shown as asterisks). There is a clear tendency for disparities to increase with the relative size of the total minority population in the suburbs. And although the regression line for blacks is above the line for Asians and Hispanics (combined here for simplicity), it has a similar positive slope for both groups.

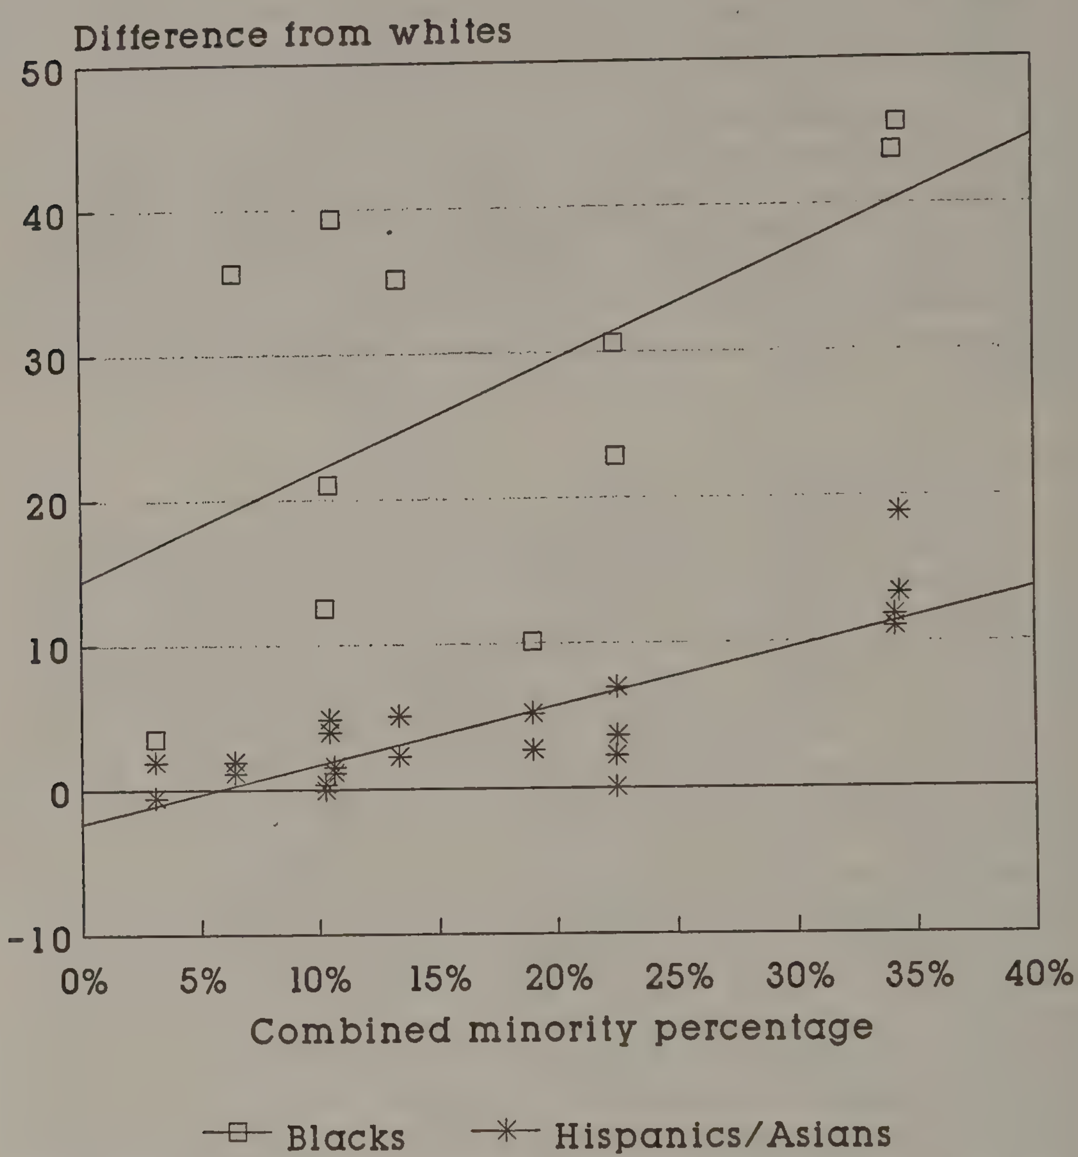
Summary and Conclusion

As others have pointed out, it is hazardous to draw inferences about processes affecting individuals from aggregate data, and it can also be risky to draw region-level conclusions from aggregate data without controlling for microlevel processes. Our approach is to model segregation (specifically, its inverse, coresidence with whites) in a multilevel fashion, disentangling the segregation processes occurring at the level of individuals (for a particular group and region) from those at the level of suburban regions (aspects of locational dynamics that affect all group members in the region). In this way, our procedure meets one of the long-standing goals of segregation research — to remove the effects of obvious determinants of location such as income from segregation measures (see, e.g., Farley & Allen 1987; Massey & Denton 1993).

We find, in brief, that several variables operate at the individual level to affect the racial composition of suburbs in which a person lives. These are not the same for every racial/ethnic group, but they include income, education, home ownership, nativity, and language. There is some indication that a few of these variables also have effects at the aggregate level in our sample. After controlling for individual processes, the zero-order correlations suggest that Asians are more integrated with whites in regions where the average education level of Asians is higher, and Hispanics are more integrated in regions where Hispanics are more assimilated. No such effects are found for blacks, however. For example, higher-income blacks live in whiter suburbs, but the difference between where a black person lives and where a comparable white person lives is not affected by the average level of black income in the region.

The one consistent regional effect is the effect of minority group size, which is found for all three groups in the correlations and also in the pooled regression equation. The clearest effect is that of the combined size of all three minorities. This is a true contextual effect: the disparity in residential location between minorities and comparable whites is greater in those regions with larger minority populations. We consider the evidence for this relationship to be

FIGURE 1: Difference in Predicted Percentage White for White vs. Minority Persons



strong. It should be pointed out, though, that different results might be found in a larger and more diverse sample of regions.

Aspects of both major theoretical models in the literature are supported in our findings. We do not assume that members of minority groups prefer to live in largely white areas. But segregation is a prime indicator of race relations: the assimilation model anticipates that segregation will decline as two groups become more similar in other respects, while the stratification model expects that segregation will prove more durable.

As the assimilation model asserts (hypothesis 1), higher income and education of individuals do result in greater residential exposure to whites for all minorities, blacks as well as Asians and Hispanics. As that model also

indicates (hypothesis 2), individual assimilation has some strong effects on proximity to whites, at least for Hispanics. However, such effects are missing for Asians, outside of two West Coast metropolitan regions where large Asian populations have established residential enclaves. This curious discrepancy between the major immigrant populations suggests differences in the process of residential segregation that deserve further conceptual and empirical investigation.

Additional support for the assimilation model comes from comparison of predicted values of racial composition for several standard types of people. The predicted values — in effect, net levels of segregation — indicate that the segregation of African Americans from whites is substantial, although somewhat smaller than unadjusted segregation scores would indicate. More relevant for the assimilation model is that Hispanics and Asians experience less net segregation than blacks, and those with the most favored background characteristics (high socioeconomic status for Asians, high socioeconomic status and good English-language ability for Hispanics) actually live in suburbs whose racial composition is similar to those of comparable whites (supporting hypothesis 4). Implied, of course, is that the segregation found for these groups in aggregate indices reflects the residential patterns for low-SES individuals and, in the case of Hispanics, for those who do not speak English fluently. There are some additional provisos concerning group differences within these two large populations. These assimilatory patterns do not apply to black Hispanics in general; and in particular regions, the largest Hispanic group for the region (e.g., Cubans in Miami) tends to be more segregated from whites than others.

The nearly complete residential integration of socioeconomically mobile Asians and Hispanics is contradictory to the notion of voluntary segregation of these groups. The most advantaged members, presumably, have the greatest choice of where to live. It appears that their preference — at least for those who live in the suburbs — is integration. If there is also a tendency of self-segregation, perhaps it is largely a central city phenomenon.

The stratification model finds support in several aspects of our results. The effects of a dual-housing market may be discerned in the negative impact of home ownership on blacks' residential integration with whites, a clear departure from the typically positive effects of other socioeconomic variables. Ownership is found to have mixed effects even for Hispanics and Asians, suggesting that the dual-housing market may have relevance for some new immigrant groups. On the regional plane, the positive relationship between group size and segregation from whites supports long-standing hypotheses emanating from researchers working within both theoretical frameworks. It is most consistent with the basic reasoning underlying the stratification model: that whites use segregation to preserve their social position in the face of a threatening — that is, large — minority advance (hypothesis 6).

Our results, it must be underscored, are limited to the suburban portions of the 11 largest consolidated metropolitan regions (CMSAs) in the country for 1980. The limitation of our analysis to suburbs cuts in two different ways. On the one hand, the selection of suburban communities as the geographic units for measuring segregation is justified by the notion, intrinsic to the stratification model, that communities are collective actors in the process of place stratifica-

tion. On the other, as Massey and Denton (1987, 1988) have argued, suburbanization is a key step in the process of residential integration for minorities, and the resulting greater integration with the majority should be reflected in less overall sorting of individuals into communities based on race and ethnicity and other characteristics. Thus, it is revealing that we have nevertheless found striking relationships between individual characteristics and the racial and ethnic compositions of the communities in which individuals reside.

These relationships may prove even stronger in analyses of location within the metropolitan area as a whole. Such analyses necessarily depend on using census tracts as the geographical units and represent one extension of the research program represented here. Another extension involves the metropolitan-area sample. The areas we have analyzed are not only the largest but, in general, the most racially and ethnically diverse. To the extent that the results of our models are consistent from region to region, conclusions from them can probably be safely extrapolated to other large and racially diverse areas. Nevertheless, it would be preferable to have a larger sample of regions, especially for the purpose of multivariate analysis across regions. And it is possible that results for smaller and less racially diverse areas may differ from those presented here. For both these extensions, our method of constructing locational attainment models provides a viable way of implementing the multilevel approach necessary for a convincing analysis of residential segregation.

Notes

1. Some boundary problems, minor for the most part, result from this choice. They stem from the fact that we must define the same geographic terrain in two different data sources — Summary Tape Files and Public Use Microdata Samples. The problems are not at the metropolitan level: since metropolitan regions and the geography of the PUMS data are both defined by county, it is not hard to make the metropolitan boundaries coincide fairly well in the two data sources. When discrepancies, typically involving small counties, arose, we generally dropped these counties from the analysis, thus forcing coincidence.

More significant divergences arise, however, because our study is focused on suburbs and thus central-city residents must be excluded. This is easily done in data from the Summary Tape Files, but not always in the PUMS. Small central cities (such as Sayreville, New Jersey, with a population under 30,000 in 1980) do occur in most of the metropolitan areas in our analysis and are not identifiable in the PUMS data we are using (A geography). Their residents are therefore included in our PUMS calculations, creating a small error in the sample definitions. The largest discrepancy occurs in Boston, where only Boston and Worcester can be identified and excluded in the PUMS analysis. Several smaller central cities with a total population of 665,000 are necessarily included (Brockton, Fall River, Haverhill, Lawrence, Lowell, New Bedford, Manchester, and Nashua). To evaluate the effect of this discrepancy, we reanalyzed this region as though these cities were suburban places (i.e., matching the PUMS and STF geography more exactly), and found substantially the same results.

2. Accordingly, interpretation of the effects of the demographic variables requires special care, and we will not focus on them. The crux of the matter is that some categories of both the age and household composition variables are necessitated by omissions from other variables (for additional discussion of this feature of the methodology as applied to the 1980 census, see Alba & Logan 1992-93). For instance, explicit representation of the group-quarters category is necessary in order to interpret properly variables such as household income, which are meaningful only for individuals in households. Unless a group-quarters dummy variable is included in the model, the omitted category for household income would implicitly mix the

group-quarters population into the lowest-income category, obviously muddying the interpretation. The problem cannot be solved by eliminating the group-quarters population, because the analysis depends on tabulations (e.g., for nativity/year of immigration) in which individuals in households and those in group quarters are inseparably mixed.

In like fashion, age categories accounting for the population younger than 25 are required by the education variable, which is defined only for persons 25 and older. The youngest age category is also required for the language variable, which has meaning only for persons aged 5 and older.

3. We consider several different "profiles" in order to summarize the net effects of variations in socioeconomic and assimilation status. For instance, in analyzing the regional determinants of segregation levels (Table 4), predicted values are for persons with the median or modal characteristics age 25-64, married couple household, native born, speaks only English, homeowner, income $20,000-29,999 and high school graduate.

4. Our equations for whites included dummy variables representing such ethnic subgroups as single-ancestry French, German, Italian, and other national origins. In some regions these variables have significant coefficients, but these are small and inconsistent (e.g., Italians tend to live in whiter suburbs in Detroit and Miami but less white suburbs in Washington). In line with the results for cultural assimilation variables, this suggests again that white ethnicity is not an important factor. For Asians, our equations included dummy variables representing Japanese, Korean, Chinese, Filipino, Indian, and Vietnamese national origins. The largest number of significant positive effects is for Japanese (positive in 7 regions, negative in 1), Koreans (positive in 6 regions, negative in 1), and Chinese (positive in 5 regions, negative in 2). The largest number of significant negative effects is for Filipinos (4 negative, 2 positive). This set of results suggests that there may be a hierarchy of Asian groups in suburbia, although clearly it is not uniform across regions.

Attitudes on Residential Integration: Perceived Status Differences, Mere In-Group Preference, or Racial Prejudice?*

LAWRENCE BOBO, *University of California, Los Angeles*
CAMILLE L. ZUBRINSKY, *The Ohio State University*

Abstract

Residential segregation, especially of blacks from whites, remains the common pattern in urban America. This research examines the part that popular attitudes on residential integration may play in the process of residential integration/segregation. Using data from a large multiethnic sample survey in Los Angeles, we examine three hypotheses about the nature of attitudes toward residential integration. The perceived economic status difference hypothesis holds that attitudes about racial residential integration rest upon assumptions about likely class background differences between ethnic groups. The mere in-group preference hypothesis suggests that ethnocentrism results in mutual across-group preferences for residential contact with in-group members. The prejudice hypothesis suggests that hostile attitudes toward an out-group shape views on residential integration. Little evidence in support of the perceived economic status difference and mere in-group preference hypotheses can be found. Theories of prejudice, in particular Blumer's theory of group position, provide much greater leverage on residential integration attitudes. We discuss the implications of the results for actual behavior and aggregate patterns of racial residential segregation.

Racial residential segregation is arguably the "structural linchpin" of American race relations (Bobo 1989; Pettigrew 1979). Analyses of 1980 census data showed that in 16 large metropolitan areas — including Los Angeles — blacks were "hypersegregated" from whites, exhibiting extreme isolation across at least four of five standard indicators (Massey & Denton 1989). Although some modest improvement occurred between 1980 and 1990, blacks remain highly segregated from whites and substantially more isolated from whites than either Asians or Hispanics (Farley & Frey 1994).

* *The authors wish to thank Mia Tuan and two anonymous Social Forces reviewers for their comments on an earlier version of this paper. There are strong reasons to believe that interethnic attitudes play a part in the problem of residential segregation. In particular, the distinctly high rates of black-white segregation would appear to call for attention to potential structures of racial attitude and preference in the population. As Massey and Denton (1989:389) argued: "Blacks are thus unique in experiencing multidimensional hypersegregation. The contrast between them and Hispanics is not easily explained by different socioeconomic characteristics, varying population sizes, different regional locations, or contrasting metropolitan conditions. Although our models cannot eliminate the view that some unmeasured objective factor accounts for the discrepancy between blacks and Hispanics, the models lend credence to the view that blacks remain the object of significantly higher levels of Anglo prejudice than Hispanics." Indeed, the degree of black residential isolation is so unique and persistent that it prompted Massey and Denton (1993) to label the phenomenon "American Apartheid," concluding that racial residential segregation is central to the development and persistence of an urban underclass that is disproportionately African American.

Others have challenged the view that uniquely potent levels of antiblack prejudice and discrimination contribute to the higher levels of black segregation from whites. For example, a number of econometric analyses emphasize such factors as economic status differences, job location, and other differences in tastes as contributing to racial residential segregation (Berry 1979; Leven et al. 1976). A central factor may be mutual patterns of in-group preference as opposed to out-group avoidance or hostility. Clark (1986, 1992) argued that the degree of joint preference among whites and blacks for living near substantial concentrations of coracial/coethnic group members is probably a larger factor in explaining modern residential segregation than white avoidance and discrimination.

Our broad objective in this research is to understand the climate of attitudes, beliefs, and opinions about racial residential segregation. We bring three objectives to the research. First, we wish to characterize the current levels of expressed preference for social distance from members of different racial and ethnic group backgrounds. Such preferences have implications for likely patterns of individual and institutional discrimination in the housing market. Second, we specifically test social psychological aspects of the perceived social class differences, the mere in-group preferences, and the prejudice models as they might influence patterns of residential segregation. Third, in recognition of the increasing diversity of many major metropolitan areas, our research is multiethnic in scope, examining the attitudes of blacks, whites, Hispanics, and Asians.[1] One possibility is that increasing ethnic diversity creates a "buffer," opening to blacks more opportunity for residential mobility and contact with whites.

Views on Racial Residential Segregation

Many factors may contribute to and constrain an individual's choice of housing location: cost and affordability, location, the quality of housing stock, proximity to work, stage in the life cycle, quality of schools, and so on (Galster 1988).

Aggregate patterns of segregation by racial/ethnic group membership can thus stem from any of several individual-level processes. With respect to understanding patterns of specifically racial residential preferences, three hypotheses are typically considered. These hypotheses are, first, that perceived differences in socioeconomic status that heavily coincide with racial/ethnic boundaries contribute to racial residential preferences; second, that members of all social groups tend to be ethnocentric, expressing preference for association and interaction with fellow racial/ethnic group members; and third, that more active out-group avoidance or domination are at the root of racial residential preferences. We elaborate on each of these models below.

THE PERCEIVED SOCIAL CLASS DIFFERENCE HYPOTHESIS

According to this view, racially/ethnically segregated neighborhoods are the result of perceived group differences in socioeconomic status characteristics: income, occupation, and associated differences in life-style (see Jackman & Jackman 1983 on class identities as involving life-style considerations). These perceived status differences are influential both within and across groups such that, "except for the genuinely poor, all people — white and black, rich and not so rich, are willing to pay, and substantially, to avoid class integration. . . . Rising above humble origins to make it in the new and better neighborhood is central to our societal tradition. Without passing judgment on it we must acknowledge the tradition, and we certainly do not seek policies to destroy it" (Leven et al. 1976:202-3). Clark (1988) draws attention to a number of social class characteristics that would increase opposition to having blacks as neighbors. He argues that, in addition to differences in wealth, black households are more likely to have a female head, unemployed adults, and more residents per household. These characteristics leave black home seekers at a disadvantage, not because of their race, but because of class-based differences in the potential for wear and tear to property, lower incomes, and unstable employment patterns.

Thus, under this model, minority group members — particularly blacks — are said to live in segregated areas because they are perceived as lacking the material and cultural-class-based resources needed to obtain housing in more desirable, predominantly white suburban areas. Under this hypothesis, we should find that the more individuals perceive that members of an out-group lag behind his or her own racial/ethnic group socioeconomically, the greater the objection to substantial residential contact with that group.

Despite the commonsense appeal and plausibility of this hypothesis, there is little evidence supporting it. Galster's (1988) comprehensive review concluded that affordability and other race-neutral economic factors (e.g., job location) accounted for at best a small fraction of black-white residential segregation. The bulk of evidence supporting this perspective comes from survey questions in which respondents are asked to explain why groups — usually blacks and whites — tend to live in separate neighborhoods, and/or the extent to which groups are perceived as having the ability to pay for housing in particular areas (Farley et al. 1993; Farley et al. 1978). Black-white comparisons of actual housing expenditures indicate a great deal of overlap, suggesting that many blacks can, indeed, afford to live in "desirable" neighborhoods (Farley et al. 1993).[2]

Likewise, inaccurate knowledge of the cost of housing cannot account for black-white levels of segregation. In 1976, blacks and whites in the Detroit area possessed accurate knowledge of housing prices in the greater Detroit area; by 1992, both blacks and whites tended to overestimate the cost of suburban housing (Farley et al. 1993:11-12). Despite this change, blacks and whites reported extensive and accurate knowledge of blacks' financial capabilities, with both groups recognizing that significant numbers of blacks can, indeed, afford to live in suburban areas (14).

THE MERE IN-GROUP PREFERENCE HYPOTHESIS

Contrary to analyses of residential segregation that give center stage to "white avoidance" or to institutional discrimination (Pearce 1979; Yinger 1986), Clark (1992) asserts the primary importance of in-group preferences. By in-group preferences he refers to "strong desires for own-race combinations in the ethnicity of neighborhoods" (451). These preferences are interpreted as a simple and natural ethnocentrism rather than anti-out-group sentiment or an effort to preserve relative status advantages. Clark argues that there are "strong similarities in own-race preferences among different ethnic groups" (463-64), and that "discrimination in the housing market plays only a minor role" (452). The preferred racial/ethnic composition of a neighborhood is simply one of many characteristics taken into consideration when searching for housing. What is more, under this model, preferences themselves are driven by positive feelings about one's own group, not negative feelings about out-groups. These ethnocentric feelings act in concert with group differences in economic status to explain the bulk of residential segregation: segregation results from the mutually ethnocentric social preferences of consumers (Clark 1986:108-9).[3] Under this hypothesis, strong feelings of in-group attachment or affect should increase objections to substantial residential integration with members of other groups.

Two immediate problems arise with the in-group preference hypothesis. While many individuals may attribute segregation to mutual ethnocentrism, such an account may function as a convenient mask or excuse for those who do not wish to express out-group prejudices more directly. Farley et al. (1994) asked respondents to the 1992 Detroit Area Study to explain why blacks and whites generally lived in different neighborhoods. Variants of the "mere in-group preference" argument were the most common answer, with 30% of whites opining that "birds of a feather flock together" or that "people just prefer it that way." Detailed analysis, however, shows that large fractions of white DAS respondents expressed negative stereotypes of blacks. They were especially inclined to do so when asked why they would not live in neighborhoods with large numbers of blacks.

In addition, emphasizing in-group preferences — positive in-group affect or ethnocentrism — as opposed to prejudice to explain persisting racial residential segregation minimizes the extent to which the preferences of one group constrain the preferences of other groups, particularly blacks. If more than token numbers of black neighbors are "seen as threatening to white households" (Clark 1991:3), and this threat results in avoidance behavior or "white flight," this would seem to indicate the presence of something more closely resembling

negative out-group affect. If preferences for same-race neighborhoods were equal across groups, and were accompanied by assurances of equal quality of life across groups, it might be persuasive to view in-group preferences as neutral. However, because of the manifestly racist historical origins of residential segregation in the U.S. (Cell 1981; Jaynes & Williams 1989; Woodward 1974) and because its effects are not neutral in their consequences (Massey & Denton 1993), it seems shortsighted to consider them neutral.

THE PREJUDICE HYPOTHESIS

Two variants of the prejudice hypothesis are relevant to attitudes toward residential integration. The first is closer to *traditional prejudice* and, in contrast to the mere in-group preference hypothesis, stresses the importance of out-group hostility in determining individual attitudes about residential contact (Allport 1954; Katz 1991; Pettigrew 1982). Prejudice is typically defined as an irrational antipathy against minority groups and their members. Prejudice is understood as heavily imbued with negative affect and negative stereotypes that make the views of the prejudiced individual unreceptive to reason and new information (Jackman 1994). Accordingly, under the traditional prejudice hypothesis we should find that measures of negative affective response to out-group members and of negative stereotypes should be the most strongly associated with objections to residential integration.

A second variant of the prejudice hypothesis is rooted in Blumer's (1958) theory of race prejudice as *a sense of group position*. Rather than placing negative feelings and beliefs at the core of prejudice, Blumer argued that prejudice involves a commitment to a specific group status or *relative* group position. The group position hypothesis suggests that neither mere in-group preference nor out-group hostility are sufficient to give prejudice social force. Instead, what matters is the magnitude or degree of difference that in-group members have socially learned to expect and maintain relative to members of specific out-groups. As a result, under the sense of group position hypothesis, it is the degree of difference between in-group attachment and out-group hostility that should be most strongly associated with objections to residential integration (see Bobo 1988). The greater the affective differentiation from members of an out-group, with such differentiation understood as one indicator of a preferred superior group position, the greater the likelihood of objections to residential integration.

Both the traditional prejudice hypothesis and group position as prejudice hypothesis view residential segregation as connected to attitudes about an out-group. As such, racial residential segregation persists because "whites prefer and are willing to pay more for segregation than blacks are willing [or able] to pay for integration" (Muth 1986:9). Several types of research on attitudinal data point to the plausibility of the prejudice hypothesis. To be sure, there has been a sweeping rise in whites' advocacy of the *principle* of free residential choice for blacks. Trend studies have shown, however, that whites still express great opposition to the enforcement of blacks' right to live wherever they can afford (Bobo, Schuman & Steeh 1986; Pettigrew 1973, 1979; Schuman, Steeh & Bobo 1985). Experimental data have also shown many whites to express greater

residential social distance from blacks than from Asians (Schuman & Bobo 1988).

Data and Measures

The data for testing these several views of residential integration attitudes come from the 1992 Los Angeles County Social Survey (Institute for Social Science Research 1992; hereafter LACSS). The LACSS is a countywide telephone survey of adults living in households selected by random dialing of digits. In addition to the general countywide sample, oversamples of telephone numbers in ZIP code areas of high black concentration (65% or more) and of high Asian concentration (30% or more) were used to efficiently generate larger numbers of black and Asian respondents. To fully capture the views and opinions of Los Angeles's very large Latino population, a Spanish language translation of the questionnaire was developed. Monolingual Spanish speakers and those preferring to conduct the interview in Spanish were interviewed in Spanish.

There were a total of 1,869 respondents, with 625 white, 483 black, 477 Latino, and 284 Asian respondents. The split-ballot design for some measures resulted in fewer cases for portions of the analysis.

Interviews were conducted by trained student interviewers taking part in a survey research methods course and by the regular interviewing staff of the Survey Research Center. The student interviewers received 12 hours of training. The LACSS procedure is to attempt a telephone number 12 times, systematically varying the day of the week and time of day before dropping it from the sample. The questionnaire averaged 38 minutes in length. The study had an overall cooperation rate of 55%. Within each major racial/ethnic group the distribution of sample characteristics on key social background factors closely resemble data from the 1990 census (see Bobo et al. 1992).[4] A systematic analysis of potential nonresponse bias, based on the procedure recommended by O'Neil (1979), indicated no pattern of significant nonresponse bias (Greenwell, Strohm & Bobo 1994).

Results

RESIDENTIAL INTEGRATION ATTITUDES

In order to tap views on racial residential integration, the 1992 LACSS included a series of questions that asked each respondent whether he or she would strongly favor, favor, neither favor nor oppose, oppose, or strongly oppose living in a neighborhood where half of their neighbors would be (in the case of white respondents) blacks, or Latinos, or Asians. Members of each major racial/ethnic category were asked about each potential out-group. In the current research, we choose to ask about a neighborhood composed of "half" members of another racial/ethnic group in order to effectively pose the issue of the importance of race/ethnic makeup to the respondent. Mentioning a half other race/ethnicity neighborhood immediately suggests substantial integration but does not go the further step of putting the respondent in a minority status,

which would raise an additional conceptual issue. The distribution of responses, combining "oppose" and "strongly oppose" responses, are shown by race/ethnicity of respondent and by target group in Table 1.

We should first note that, in an absolute sense, at least compared to actual levels of racial residential segregation, these numbers suggest substantial openness to residential integration in the mass public. For example, as Table 1 shows, just 34% of whites said that they were opposed or strongly opposed to living in a neighborhood where *half* of their neighbors would be black. Another 46% offered neutral opinions, and 1 in 5 said they would favor or strongly favor living in such a highly integrated area. To a degree, this may reflect a bias of socially desirable responses, with many respondents, whites in particular, unwilling to voice objections to residential contact with minorities. Yet we do not believe the pattern reflects a serious response bias of this kind, nor does it constitute a sharp disjuncture with actual patterns of racial residential segregation. Respondents did not give unreflective pro-integration responses. First, and most important, it is immediately apparent that members of each group react differently to each minority group. The rate of whites' objections to residential integration with Asians, for instance, is 12% lower than that observed when asked about blacks. Similarly, the rate of Asian objections to residential contact with blacks is nearly twice as high as that for potential contact with Hispanics and about six times as high as that for potential contact with whites. Second, awareness of the general perception of blacks as the least desirable neighbors, a perception reflected in these results, may be more consequential for individual housing choices and location than a deeply held personal aversion. Blacks may be discouraged by the unpredictable reaction from a relatively small number of not easily identified, potentially hostile whites from moving into predominantly white neighborhoods. At minimum, in rank order of groups, the attitudinal data closely mirror the findings from more objective measures.

Several other patterns emerge. Only a trivial percentage of blacks, Hispanics, and Asians express objection to living in a largely white neighborhood. The figure is below 10% for each of the minority groups. This is consistent with the assumption that greater residential contact with whites is typically seen as being associated with upward social mobility and access to better neighborhoods and services.

Blacks are clearly the least preferred potential neighbors. The highest rates of objection to interracial residential settings occurs when blacks are the target group of potential contact. Fully 46% of Asians object to living in a half black neighborhood and a least a third of both whites and Hispanics express similar objections. If viewed as a rank order of preferences in the population as a whole, then, blacks are unequivocally at the bottom of the preference hierarchy and whites just as unequivocally are at the top.

Black respondents are the least likely to object to residential integration. White respondents are the most likely to object to interracial residential contact, with but one exception (i.e., Asians are more strongly opposed to contact with blacks). All in all, these patterns strongly suggest the presence of a well-defined racial rank order with respect to housing. In this racial order, blacks are the bottom group, at once most open to integrated living with members of other groups and yet confronting the most resistance from other groups.

TABLE 1: Race and Residential Integration Attitudes Objections to Residential Integration with Out-Groups, by Race/Ethnicity

	Respondent Race

	(618)	(478)	(472)	—
$\chi^2 = 47.00$				
df = 8				
$p < .0001$				

In order to understand the social bases of these attitudes, we examined the percentage objecting to residential integration by race of respondent, race of target group of the question, and several major social background variables (respondent age, education, occupation, sex, family income, and nativity). In general, these results suggest infrequent and small effects of these background factors on residential integration attitudes. Out of 72 tests, only 21 attain conventional criteria of significance.[5]

Nonetheless, several of these patterns are worthy of note. First, among white respondents, the data consistently show that the lower the level of education, the higher the likelihood of objecting to residential integration. Second, there is a slight tendency for younger white and black respondents to express greater opposition to contact with Hispanics and Asians than do their older coethnics. Third, nativity sometimes influences the residential segregation views of Hispanics and Asians, though in opposite directions. Foreign-born

Asians are highly likely to object to residential integration with blacks. Native-born Latinos are more likely to object to residential integration with blacks and whites than are foreign-born Latinos.

IN-GROUP PREFERENCE HYPOTHESIS

Our primary analytical task in the remainder of this article is to understand the possible sources of individuals' racial residential integration attitudes. Clark (1986, 1992) argued that in-group preference was a substantial factor in racial residential preferences. We measured in-group attachment with a widely used procedure known as a feeling thermometer. Respondents were asked to rate each of several social groups on a scale running from 0 degrees, which represented extremely cold feelings, to 100 degrees, which represented extremely warm feelings, and where 50 represented neutral feelings. This approach to tapping affective reactions to issues, candidates, and social groups has been widely used in the literature on intergroup attitudes within sociology (Bobo 1988; Jackman 1977; Jackman & Muha 1984; Schuman, Steeh & Bobo 1985), and political psychology (Sears 1988). We asked respondents to rate their own group, and each of the other major racial/ethnic groups on the thermometer scales. The mean scores by race are shown in Table 2.

Consistent with Clark's "mere in-group preference" hypothesis, all groups express in-group preferences. That is, the in-group thermometer rating is on average the highest absolute rating given by members of each group (highest scores run along the diagonal). Furthermore, by a slight margin blacks have the highest in-group affective rating — 71.2 — followed by Hispanics at 68.3, then whites at 66.3 and Asians at 65.0. A pattern worthy of note is that minorities consistently give whites higher affective ratings than they do to other out-groups. In other words, the highest average out-group rating among minorities comes in reaction to whites, not in reaction to members of another minority group. This pattern again points to the presence of an American racial rank order, with whites *consensually* regarded as occupying the most preferred social position.

These thermometer measures allow us to test aspects of the mere in-group preference hypothesis. Table 3 shows the Pearson correlation coefficient for the in-group thermometer rating and each of the racial residential integration questions by respondent race/ethnicity. As is immediately evident, in-group affect has a uniformly weak relation to racial residential integration attitudes. In only one instance does the correlation rise above .10 (blacks' reactions to Hispanics, $r = -.13$), and in this case the effect is in the wrong direction, suggesting that as positive in-group feeling increases among blacks, opposition to residential integration with Hispanics tends to decrease. This first-cut analysis suggests that mere in-group preference is not likely to be a substantial determinant of whites' reactions to racial residential integration or to the reactions of blacks, Hispanics, or Asians either.

TABLE 2: Race and Mean Feeling Thermometer Ratings Thermometer Scales[a]

	Respondent Race				
	White	Black	Hispanic	Asian	f
Group rated					
Whites	66.3	61.4	62.8	62.1	6.03***
Blacks	58.4	71.2	55.4	53.1	59.50***
Hispanics	58.8	58.9	68.3	53.7	32.50***
Asians	58.8	55.2	55.5	65.0	14.96***

IS IT PREJUDICE?

The thermometer ratings also allow us to test aspects of the two prejudice-based hypotheses about attitudes on racial residential segregation. It is possible that affective hostility to an out-group is a more substantial element of racial residential preferences than mere in-group preference. To examine this possibility, the second row of figures in each target-group block of Table 3 reports the correlation between racial residential integration attitudes and the appropriate out-group thermometer rating. Among all groups, the out-group affective rating is more strongly correlated with residential integration attitudes than mere in-group preference. The general pattern is that as the out-group affective rating improves, opposition to interracial residential contact with members of that group tends to decline.

We can also test aspects of the group position model of prejudice as a basis of racial residential integration attitudes. Under this model, it is ideas and beliefs about the relative group positions that constitute the psychological core of prejudice, not merely in-group attachment or out-group aversion. We attempt to capture such positional commitments with a difference score that involves subtracting an individual respondent's rating of each out-group from his or her in-group rating using the thermometers. We refer to this measure as a difference score or affective differentiation measure. The third row of each target-group block of figures shows the correlation between the affective differentiation measure and the racial residential integration attitudes measure.

The affective difference measure is the strongest correlate of racial residential integration attitudes among whites. In each case, for white respondents the correlation exceeds .3, and it reaches .43 in the case of reactions to living in a half Asian neighborhood. In short, as the affective difference that whites prefer to maintain between themselves and members of minority groups rises, so does the level of opposition to racial residential integration. Consistent with the group position model then, there appears to be something status-oriented

TABLE 3: Correlation of In-Group Affect, Out-Group Affect, and Affective Differentiation with Residential Integration Attitudes[a]

and positional underlying whites' reactions to the possibility of substantial racial residential integration, not simply in-group preference or out-group aversion.

The affective differentiation measures, although consistently stronger correlates of residential integration attitudes than mere in-group preference, usually exhibit weaker correlations than simple out-group ratings among minority respondents. For blacks, Hispanics, and Asians the correlation between the affective differentiation measure and residential integration attitudes is always weaker, and sometimes substantially so (e.g., .17 versus -.30 for blacks' reactions to Hispanics), than the correlation with the out-group affective rating alone. This immediately implies that status and positional issues have less to do with how minority respondents form their attitudes on residential integration than is apparently true of whites.

We wished to gain greater leverage on racial prejudice as a possible source of attitudes on residential integration. To do so, we also examined how measures of racial stereotypes relate to the racial residential integration attitudes.[6] Table 4 shows, by race/ethnicity of respondent and of the target group of the question, mean scores on a series of bipolar trait rating scales. Each item and the overall scales range from 1 to 7, with a score of 4 as a neutral or

mid point. Each item has been scored so that higher scores reflect more negative ratings on the dimensions of intelligence, welfare dependency, and difficulty to get along with socially. Time constraints made it impossible to ask about a much wider set of traits, but these three were chosen on substantive grounds. Intelligence is a classic issue in intergroup relations. In an achievement-oriented society such as the U.S., intelligence is often credited with explaining socio-economic success or failure and a host of other social and behavioral outcomes, such as involvement in crime. Welfare dependency has been a longstanding aspect of antiblack stereotypes in the U.S. and may be increasing as an aspect of stereotypes of Latinos as well. The "hard to get along with" dimension was included because of the widespread discussion that many recent Asian immigrant groups, especially but not exclusively Koreans, have brought cultural styles of interaction that are more brusque than is typical of U.S. culture. Hence, we expect that this set of traits taps critical dimensions of minority group stereotypes that are likely to have bearing on willingness to share residential space with minority group members.

The rows of Table 4 within each target-group block report the mean rating on each of three trait dimensions, and the fourth row reports an average stereotype score based on all three traits. The figures in parentheses report the Pearson correlation for each trait measure and the stereotype indexes with the racial residential integration attitudes. Among whites in particular, the results suggest that negative stereotypes are an element of how individuals form their attitudes to racial residential integration.

Consider first just the stereotypes themselves. Blacks receive the most negative overall ratings and whites, predictably, receive the most favorable overall ratings. Asians and Hispanics tend to fall in between these extremes, with ratings of Hispanics quite close to those found for blacks and ratings of Asians quite close to those found for whites. Among white, Asian, and Hispanic respondents, blacks receive the highest average negative stereotype ratings. The single most negative rating of blacks among all groups occurs on the welfare-dependency trait. There is also a tendency for welfare dependency to be the negative trait most attributed to Hispanics as well. The most negative rating of Asians occurs consistently on the "hard to get along with" dimension, as expected.

Stereotypes are usually correlated with racial residential integration attitudes. As stereotypes become more negative, opposition to residential integration tends to increase. This pattern is strongest and most consistent among white respondents, but there is also a trend in this direction among blacks, Hispanics, and Asians.

IS IT PERCEIVED SOCIAL CLASS DIFFERENCES?

Before turning to multivariate analyses, we consider the bivariate relation of perceived socioeconomic status differences and attitudes on residential integration. We tapped perceived socioeconomic status differences with two measures. The first is a simple bipolar trait-rating question that asked respondents to rank each major racial/ethnic group on a 1 to 7 continuum where 1 meant most group members "tended to be rich" and 7 meant most group

TABLE 4: Race and Mean Stereotype Trait Ratings[a]

[a] Figures are means on a 1 to 7 scale where 7 is the negative end of a bipolar rating continuum. Figures in parentheses are zero-order correlations of the stereotype measure with residential integration attitudes.

members "tended to be poor." The second measure is a difference score between a respondent's in-group rating on this measure and his or her rating of each out-group. A score of zero on this measure would thus indicate a perception of no average economic status difference between groups, positive scores would indicate a perception that one's in-group was of higher economic status than the out-group, and negative scores on the difference measure would indicate a perception that one's in-group members were of lower economic status. Results for both measures are shown in panel A of Table 5. Panel B reports the correlation of each measure, by respondent race and target group race/ethnicity, with racial residential integration attitudes.

All respondents tend to perceive a similar pattern of economic status differences between groups. In broad terms, these perceived differences conform to actual average patterns of difference in economic status (Hirschman 1983).

TABLE 5: Perceived Status Differences and Residential Integration Attitudes

Panel A: Mean Group Rating[a]

	Respondent Race			
	Whites	Blacks	Hispanics	Asians
Target group				
Whites				
Mean group rating	3.50	3.10	3.03	3.00
In-group/out-group difference	—	-1.95	-1.46	-.43
Blacks				
Mean group rating	5.04	5.03	4.71	5.17
In-group/out-group difference	1.55	—	.22	1.74
Hispanics				
Mean group rating	5.00	5.20	4.49	4.82
In-group/out-group difference	1.51	.17	—	1.40
Asians				
Mean group rating	3.51	3.65	3.33	3.42
In-group/out-group difference	.01	-1.38	-1.16	—

[a] Figures in the upper row are means on a 1 to 7 scale where 1 means "rich" and 7 means "poor." Figures in the lower row are differences scores between in-group rating and out-group rating.

Thus, blacks and Hispanics are the groups most likely to be rated toward the poor end of the continuum and Asians and whites most likely to be rated toward the rich end of the continuum. The perceived in-group versus out-group difference mirrors this pattern as well. For example, whites and Asians both see blacks and Hispanics as lagging behind them economically, but on average see little difference in economic status between one another. As panel B shows, however, neither the absolute perceived economic status nor the perceived status difference is substantially correlated with a respondent's racial residential integration attitudes. Out of 24 possible instances only 4 correlations attain significance at the .01 level, and one of these is in the wrong direction. *In sum, concern about perceived differences in economic status is unlikely to be a powerful component of how respondents form their attitudes on racial residential integration.*

It is important to determine whether the bivariate patterns summarized to this point persist in a fuller multivariate analysis. There are important differences among respondents and across groups in educational attainment, income, sex distribution, and nativity. Therefore we conducted a series of OLS regression analyses that controlled for these factors and then introduced, in separate

TABLE 5: Perceived Status Differences and Residential Integration Attitudes

models, the in-group affect measure, the out-group affect measure, and the affective differentiation measure. Each model included the perceived economic status difference measure and the stereotype index rating. These results are shown in Table 6.

In only 3 of 12 possible instances did the in-group preference measure exhibit a significant relationship with the residential social distance measure. Of note, two of these occur for whites and involve reactions to contact with the *racially* distinct out-groups: blacks and Asians. This pattern confirms the longstanding sociological observation that differences perceived as racial rather than ethnic in nature are often more socially divisive (Lieberson 1980; Stone 1985). Simple in-group favoritism is, plainly, not a powerful determinant of social distance attitudes. It has no effect whatever among Hispanic or Asian respondents and works in the wrong direction (according to the preference model) for blacks' reactions to Hispanics.

The perceived SES gap measures, with only one exception, are not related to social distance feelings. The one instance of a significant effect, ironically, is in the direction opposite to expectation. The larger the gap blacks see between

themselves and Asians, the more open they are to residential contact with Asians. In short, what an individual assumes about the average economic status of out-groups has little to do with willingness to enter a substantially integrated community.

The various prejudice measures have far more consistent and stronger effects on social distance feelings. The effects of prejudice vary with the measure and, to a degree, with the race of the respondent and the race of the target group.

The most consistent effects are found for the out-group affect measure. Across each of the 12 tests, we found that as affect toward an out-group improved, opposition to residential contact significantly declined. Indeed, even for the two occasions when in-group affect has the anticipated effect, it is clear that the increment to variance explained above the baseline model is greater for the out-group affect measure. Out-group affect matters irrespective of race of the respondent and irrespective of race of the target group.

The affective differentiation measure influences social distance feelings, particularly among white respondents. Although sometimes a significant predictor among black, Hispanic, and Asian respondents, it adds no more to the amount of variance explained and typically less than the out-group affect measure. That is, affective differentiation is a uniquely potent predictor of social distance feelings among white respondents. The implication is that they are maintaining a social status difference, as opposed to expressing mere in-group preference or out-group hostility.

Finally, negative stereotypes are typically significant predictors of social distance preferences. Negative stereotypes are most consistently important among white respondents. The effects are less consistent among minority respondents, especially among Asians, and to a degree, among Hispanics.[7]

ON LINKING ATTITUDES AND BEHAVIOR

We do not have measures of a respondent's recent residential moves or future intentions. Hence, we cannot examine whether change occurred (or might occur) in an attitude-(in)consistent manner. However, the 1992 LACSS did ask respondents to report on the main ethnic group in their neighborhoods, on whether the neighborhood was undergoing ethnic change, and if so, what the nature of the change was. A brief consideration of these data sheds a small amount of light on possible attitude-behavior connections.

Our data on reported neighborhood composition and change are both reassuringly consistent with familiar demographic analysis results and, more important, with the attitudinal patterns reported above. The upper panel of Table 7 shows that blacks are the group most likely to live among coethnics (64.7%) and the least likely to live in largely white areas (4.5%). Likewise, whites are the second most likely to report sharing residential space with coethnics (58.2%) and the least likely to report living in largely black areas (4.9%). Asians are the minority group most likely to report living in largely white areas (20.8%), a pattern supported by the high proportion of whites who report living in largely Asian areas (17.3%). Both Asians and blacks show high

proportions reporting that they live in largely Hispanic areas, 19.4% and 17.7%, respectively.[8]

The second panel shows that blacks are the group most likely to report that their neighborhoods are undergoing ethnic change (61.8%), followed by whites at 56.1%. In general, the experience of ethnic residential change is common in Los Angeles County, with roughly half of Asian and Latino respondents also reporting that their neighborhoods are undergoing change.

The nature of these changes is made a bit clearer in the lowest panel of Table 7. Among those reporting that a change was taking place, blacks overwhelmingly report (77.8%) that their neighborhoods are becoming more Hispanic. The modal response among both Latinos and Asians, however, is that their neighborhoods are experiencing an influx of coethnics, 45.5% and 66.2%, respectively. These patterns presumably reflect the high rates of new immigration for these groups (Waldinger 1989). Whites undergoing change most often report that their neighborhoods are becoming more Asian (50.3%), followed by an increasing number of Hispanics (31.1%). Few whites see their neighborhoods becoming more black. This is a telling contrast with whites' high and increasing frequency of residential contact with Asians. Blacks and Asians now constitute roughly equal proportions of the population in Los Angeles county, but whites — in a pattern directly consistent with the attitudinal results we have reported — are now far more likely to share residential space with Asians than with blacks and are far more likely than blacks to anticipate the substantial future movement of Asians into their neighborhoods.

Although we cannot test the hypothesis that attitudes directly translate into residential choices and aggregate housing patterns, the results in Table 8, which show the association between reported neighborhood composition and our residential integration attitude measure, are suggestive. First and foremost, a significant association between attitude and reported residential neighborhood composition occurs most consistently among white respondents. White respondents living in mainly white (37.2%) or mainly Asian neighborhoods (43.7%) are highly likely to object to residential integration with blacks. Whites from the same two types of communities are also the most likely to object to residential integration with Hispanics. These patterns are consistent with national survey results reported by Sigelman and Welch (1993), who find more positive racial attitudes among whites who have black neighbors.

We are much less likely to observe an association between attitude and reported residential composition among blacks, Asians, and Hispanics than among whites. The only exceptions to this case occur when blacks are the target of the residential integration question among those Latino and Asian respondents who live in coethnic-dominated neighborhoods or in largely white neighborhoods. In particular, Asian respondents living in mainly white or mainly Asian neighborhoods express the absolute highest levels of objection to residential integration with blacks, 52.7% and 50.8%, respectively.

It is impossible to judge from these data whether attitudes led to the current residential locations, or whether residential location comes to affect attitude. Cross-sectional data face a severe constraint in this regard, as others have observed (Jackman & Crane 1986). In all likelihood, there are reciprocal effects

with attitude shaping location decisions to as great an extent as resources, information, and other considerations allow, while the experience of particular neighborhoods, group relations, and status and service considerations then come to reshape attitudes (Galster 1989; Sigelman & Welch 1993).

The implications of the Table 7 and Table 8 results taken as a whole, however, tend to point in the direction of racial attitudes contributing to housing location decisions and patterns. At minimum, the data suggest that many whites living in white neighborhoods, and other minorities living in white neighborhoods or in coethnic-dominated neighborhoods are likely to resist the

entry of blacks into their communities. These results strongly parallel recent analysis by Massey and Gross (1991). They argued that, despite evidence of declining residential segregation between 1970 and 1980, there still is a very low upper bound on white willingness to share residential space with blacks. Aggregate segregation declines only to the extent that it does not increase the likelihood of black-white contact much above the 1980 average proportion of .053. Likewise, Farley and Frey (1994:40) found that the largest declines in segregation took place "in metropolitan areas in which blacks made up a small percentage of the neighborhood of the typical white."

The extraordinarily high level of black-white isolation is thus unlikely to break down quickly, even while minority groups of comparable proportionate representation in the population make substantial entry, at least relative to blacks, into white communities. The pattern of attitude distribution and dynamics we have documented seems very much a constitutive element of this process of residential mobility for some and continued apartheidlike conditions for others.

Discussion and Conclusions

We began this research with the goal of examining the mere in-group preference, perceived economic status differences, and prejudice models as hypotheses about the nature of racial residential integration attitudes. Our results provide virtually no support for the in-group preference or the perceived economic status difference hypotheses. We do find general patterns of ethnocentrism, yet ethnocentrism alone is a small component of attitudes on residential integration, irrespective of the race of the target group or of the respondent. We do find consensually held perceptions of racial/ethnic group differences in average economic status, yet these perceived differences in status play almost no role in residential integration attitudes. In short, in order to understand attitudes on racial residential integration we must be expressly concerned with views about other racial/ethnic groups.

Prejudice does appear to be an important element of how respondents form their views on residential integration. The type or form of prejudice that shapes residential integration attitudes appears to depend, however, on majority or dominant group status versus minority or subordinate group status. We find that among white respondents the affective differentiation measure is a strong predictor of residential integration attitudes. Its effects always exceed those of in-group preference and of out-group hostility. In addition, the stereotyping measure is consistently influential among white respondents, irrespective of the minority target group. Among minority respondents it is more often the case that out-group hostility exceeds affective differentiation in importance. What is more, the effects of stereotyping are a good deal less consistent for minority respondents.

We believe that the best substantive reconciliation of these incommensurate patterns is to acknowledge that the U.S. has a relatively clear-cut racial/ethnic hierarchy, or racial order, at least at its top and bottom ranks. The historical and present dominant social group is white Americans. The historical (and at least

perceptually, if not also in fact) present bottom group is African Americans. (See Jaynes & Williams 1989; Massey & Denton 1993.) For blacks, Latinos, and Asians, economic and social advancement is associated with greater proximity and similarity to white Americans. For whites, integration — especially with blacks — brings the threat of a loss of relative status advantages. As a result, attitudes on an issue like racial residential integration are likely to have very different meanings to whites than to members of any of the minority groups, even comparatively affluent Asians. Until such time as Asians have long occupied a status of comparable socioeconomic status with whites, even members of this group should view the prospect of residential contact with whites as upward mobility. Whites are the group, then, most likely to view any increased racial residential integration — with any other group — as changing traditional status relations of relative dominance and privilege. That is, they tend to view integration with any of the minority groups as threatening or undermining a previous status relation of superiority. It is for this reason, we speculate, that the affective differentiation measure assumes greater importance to the attitudes of whites than it does for any of the minorities. Minorities cannot view one another as threats to a traditionally privileged status in quite this fashion. Instead, if minorities express aversion to residential contact with members of other groups, it tends to be based more directly on affective hostility to that group, not an effort to preserve a longstanding relation of privileged status.

Our analysis can be read both positively and negatively. Two aspects of our results suggest that racial residential segregation may continue its gradual decline. First, average levels of openness to substantial integration, even among whites in reaction to large numbers of black neighbors, was fairly high. Second, the basic human tendency toward ethnocentrism, although evident in our data, has comparatively little to do with attitudes on racial residential integration. Both these patterns are consistent with the general trend toward more tolerant racial attitudes (Schuman, Steeh & Bobo 1985) and modest declines in actual levels of residential segregation (Farley & Frey 1994).

These sanguine results notwithstanding, we believe that on balance our analysis is consistent with the conclusions of Farley et al. (1994), Galster (1988), Massey and Denton (1993), Yinger (1986), and others who argue that both individual and institutional discrimination still contribute to the high levels of racial residential segregation. Negative stereotypes of blacks and Latinos are fairly common. Among whites these stereotypes and racial prejudice as a sense of group position translate into attitudes on residential integration. Among minorities, hostile feelings toward other groups shape resistance to residential integration. What is more, attitudes on residential integration appear to have a connection to actual places of residence. Each of these patterns is consistent with the mounting evidence of ongoing patterns of individual and institutional discrimination in the housing market (Turner 1992; Yinger 1991).

In particular, our results suggest that the high rates of black-white residential separation are likely to continue, even in an extraordinarily diverse metropolitan area such as Los Angeles. To be sure, Farley and Frey (1994) found that areas with larger nonblack minority populations had lower overall levels of black-white segregation in 1990. *Such communities, however, did not experience*

higher rates of decline in black-white segregation between 1980 and 1990. Our data may shed some light on this failure of the "buffer" hypothesis. A nontrivial fraction of Latinos and an even larger fraction of the Asian population hold negative stereotypes of blacks and react against the prospect of sharing residential space with blacks. Indeed, Asians were more hostile to blacks than were whites on each of our prejudice measures and in expression of residential integration attitudes. Hence, rather than operating as a "buffer" or source of greater options for blacks, ethnic diversity may in many instances simply add to the climate of resistance to blacks as neighbors.

Notes

1. It is necessary to note that we regard racial and ethnic distinctions as socially defined constructs (See & Wilson 1989; Stone 1985). Racial/ethnic categories and labels are variable across time and place in meaning as well as salience. Racial/ethnic distinctions also interact with class and gender. In designing the questionnaire, we decided to use the labels "whites," "blacks," "Asians," or "Asian Americans," and "Hispanic" or "Hispanic Americans." This decision rested on three considerations. First and foremost, our pretest results clearly indicated that these are widely used and well understood terms. Second, although it would have been ideal, it was not feasible to develop a questionnaire fully sensitive to even a limited range of national origin subgroups within the heterogeneous Latino (i.e., Mexican, Nicaraguan, Salvadoran, etc.) and Asian (i.e., Korean, Japanese, Chinese, etc.) populations. Third, there are strong reasons to believe that social interaction and discourse are often dominated by reliance upon stereotypes linked to the broad racial/ethnic categories we have used (see Bobo & Hutchings 1994 for a fuller discussion). This is not to deny the importance of variability based on national origin, class, and gender. Rather, it is a concession to the powerful evidence that racial/ethnic cues involving these four broad categories often precede and sometimes overwhelm these other group statuses in social interaction, especially where questions of racial residential integration are concerned.

2. Farley et al. (1993) show that Detroit area blacks made rent and mortgage payments comparable to those necessary for many suburban residences. Among homeowners, the black-white gap was $250; however, 60% of blacks owning homes in the central city area and 52% of suburban whites had monthly housing expenditures between $300 and $799 per month. The gap for renters was even smaller, and 61% of both blacks and whites had gross rent payments between $300 and $599 per month. Farley et al. (1993) point out that the Detroit area is characterized by a declining housing market, reporting a 6% decrease — to $68,000 — in the median price of single-family dwellings between 1980 and 1990.

3. Despite Clark's claims of neutral ethnocentrism, Clark finds that whites express the strongest preferences for having a majority of their neighbors from their own race, with almost no whites expressing interest in living in neighborhoods that are less than 50% white. Moreover, whites, Hispanics, and Asians all express the strongest desire for own-race neighbors when the target group is blacks, and blacks and Asians express the strongest desire for neighborhoods with a substantial number of whites (Clark 1992). Blacks' expressed preferences for 50/50 white neighborhoods may represent preferences for higher-quality neighborhoods, rather than a desire to live and interact with whites (Clark 1992:455). Neighborhoods with a substantial number of whites often have higher-quality schools and services, and blacks — and other excluded groups — are well aware of these differences. While there is likely to be some validity to the desire for higher-quality neighborhood services (Farley et al. 1993:22), blacks also place a great deal of importance on integration, racial harmony, and effective interaction with whites (Farley et al. 1978; Farley et al. 1993; Pettigrew 1973).

4. We compared the LACSS data to 1990 census distributions on nativity, sex, education, age, family income, and occupation. The only noteworthy differences emerged, generally, on the education variable and did so in ways typical for telephone surveys. Our sample is better educated than the population at large, particularly among blacks and Latinos. It should be

borne in mind that not all households have telephones in them and that telephone coverage varies by social class and by race/ethnicity, with whites more often living in telephone households than do blacks or Latinos (Groves & Kahn 1979; Thornberry & Massey 1988). In particular, the LACSS data underrepresented high school graduates. In addition, as a result of the large number of Asian nationality groups and languages — 19 different nations of origin were found among Asians in the sample — it was impractical to develop additional foreign language translations of the questionnaire. Thus, even though 70% of our Asian respondents were nonnatives, this figure is substantially below the 1990 census figures for Los Angeles County (88%).

5. The data are not shown, but can be obtained from the authors upon request.

6. The format of the stereotyping measures was taken directly from the 1990 General Social Survey (Bobo & Kluegel 1991; Smith 1991), which included a series of bipolar trait-rating items. The bipolar trait-rating format has been shown to increase respondent comfort in expressing racial/ethnic group distinctions (Jackman & Senter 1983), to produce evidence of much higher levels of negative stereotyping than do older forced-choice formats (e.g., compare reported perceptions of blacks as less intelligent from Schuman, Steeh & Bobo 1985 to those reported by Bobo & Kluegel 1991 and Smith 1991), and to yield reasonably reliable and valid measures of prejudice (Bobo & Kluegel 1993; Farley et al. 1994).

7. To this point our analyses strongly contradict the mere in-group preference hypothesis advanced by Clark. One possible objection to our results could be that we find a much stronger role for prejudice than for mere in-group preferences because of the dependent variable. Our residential integration measures tap out-group social distance, which differs from expression of preferred neighborhood composition. In order to see whether our results are robust using a preference dependent measure, we conducted analyses of data from the 1976 National Election Study Survey (Miller & Miller 1977). This national probability sample of adults 18 years of age or older contained feeling thermometer measures and a neighborhood preference question. The latter asked: "Would you personally prefer to live in a neighborhood that is all (white/black), mostly (white/black), about half (white/black) and half (black/white), or mostly (black/white)?" For the analyses reported below, high scores indicate responses of mostly opposite race and low scores indicate expressed preference for all same-race neighbors. Unfortunately, the 1976 NES did not include reasonable proxies for perceived economic status differences or group stereotypes.

As was found for our 1992 LACSS data, the thermometer measures for both black and white respondents reveal clear in-group preference or ethnocentrism. Blacks' mean rating for "blacks" was 86.7, as compared to 68.4 for "whites." Among whites, the mean in-group rating was 74.2 as compared to 58.8 for "blacks." Among blacks we found no significant correlation between in-group rating (r = -.08), out-group rating (r = .02), or affective differentiation (r = -.11) and responses to the neighborhood preference question. Among whites, there are significant correlations between neighborhood preference and in-group rating (r = -.23), out-group rating (r = .23), and, most important, affective differentiation (r = -.38). This pattern of associations among white respondents is consistent in the South and non-South.

OLS regression models support our earlier findings with one qualification. The strongest predictor of neighborhood preferences, net of education, age, region, sex, and family income among whites, was the affective differentiation measure. Entered singly, or jointly, however, we do find significant effects of in-group affect and of out-group affect among white NES respondents. Measures of in-group affect appear to play a stronger role when predicting a neighborhood composition preference item as opposed to a social distance item (setting aside for the moment possible change over time and sample composition differences between the 1976 NES and 1992 LACSS data). Among blacks, only the affective differentiation measure has a significant effect. On the whole, however, examination of a different dependent measure confirms key findings based on the LACSS data.

8. Patterns for the questions on perceived neighborhood racial composition parallel analysis of actual residential patterns from census data in two other important ways. First, our data are consistent with census data showing that middle class blacks are less able to translate their class status into greater residential proximity to whites (Farley & Frey 1994; Kain 1986). Eighty-one percent of blacks with family incomes of $60,000 or more reported living in mostly black neighborhoods as compared to just 11% who report living in mostly white neighborhoods. In

contrast, 33% of Asians in this high-income category reported living in largely Asian neighborhoods and an equal 33% report living in largely white areas (three times the rate for high-income blacks). Similarly, only 26% of high-income Hispanics reported living in largely Hispanic neighborhoods, and 47% reported living in largely white neighborhoods (more than four times the rate observed among blacks).

Second, among both Latinos and Asians, native respondents — more so than the foreign-born — report that they live in largely white neighborhoods (Ong, Lawrence & Davidson 1992). These figures are 19% versus 9% comparing native-born and foreign-born Latinos. The comparison for Asians is 24% versus 19%.

The Socioeconomic Assimilation of Caribbean American Blacks*

MATTHIJS KALMIJN, *Utrecht University*

Abstract

Several authors have examined whether black Caribbean immigrants are more successful in the American economy than African Americans. This study examines the earnings and occupations of Caribbean American men in the 1990 census and expands previous analyses by examining generational differences within this new black minority. Central findings suggest that: (1) There continue to be important socioeconomic differences between Caribbean American blacks and African Americans. (2) If we can speak of a "black success story," however, it is the story of British Caribbeans; blacks from the French- and Spanish-speaking Caribbean do worse than African Americans. (3) Second- and later-generation Caribbean blacks generally have higher socioeconomic status than the immigrant generation. (4) For British Caribbeans, this implies that later generations have gained further advantages on African Americans. The pattern of generational differences within the Caribbean American community generally does not support a notion of structural assimilation into the black American community.

Although Caribbean American blacks form a small group in American society, they are important from a sociological point of view in that they have a dual status, a status as "black" and a status as "immigrant." The dual status they face raises important questions about the ethnic identity they form of themselves as a group (Waters 1991), the social and political boundaries they maintain vis-á-vis native-born blacks (Kasinitz 1992), and the way they are treated in labor markets and other public spheres by the white American majority (Model 1991). One of the more intensely debated issues in this respect is the question of whether Caribbean blacks are more successful in the American economy than native-born blacks. Some authors regard Caribbean Americans as a "black success story" in a racially segregated society (Sowell 1978; Glazer & Moynihan 1964), while others believe they face the double hurdle of xenophobia and racism in the American labor market (Bryce-Laporte 1972).

The assimilation of Caribbean blacks in the U.S. has been studied as far back as the 1930s (Reid 1939), but only recently have researchers begun to

** An earlier version of this article was presented at the annual meeting of the American Sociological Association in Los Angeles in 1994. I thank Frank Dobbin for encouraging comments and helpful suggestions. Address correspondence to Department of Sociology, Utrecht University, Heidelberglaan 1, Utrecht 3584 CS, Netherlands.*

examine their socioeconomic status in a systematic fashion. In an analysis of the 1970 census, Sowell (1978) found that first- and second-generation West Indian blacks had higher family incomes and were more likely to be employed in the professions than native-born blacks. Differences were found both in the U.S. as a whole, and in the New York metropolitan area, where most West Indian blacks live. Although Sowell did not take into account differences in background characteristics, multivariate analyses of the 1970 census by Chiswick (1979) led to similar conclusions. Chiswick compared foreign-born blacks, most of whom are from the West Indies, to native-born blacks and showed that ten years after arrival, foreign-born blacks had higher annual earnings than native-born blacks, even after the influence of education and experience was taken into account. While these findings are consistent with the stereotype of Caribbeans as a black model of achievement, analyses of the 1980 census suggest that the gap between Caribbean and African Americans has narrowed. In a multivariate analyses of Caribbean immigrants in the 1980 census, Butcher (1994) shows that after controlling for education, experience, and several other background characteristics, Caribbean immigrants were more likely to be employed than African Americans. Conditional on employment, however, they did not have higher annual or weekly earnings than native-born blacks. In a comparable analysis of the 1980 census, Model (1991) found the same result for foreign-born blacks in states with large Caribbean populations (e.g., New York, Florida, Massachusetts). In their monograph of the 1980 census, Farley & Allen (1989) found no differences in earnings either, but they also showed that foreign-born blacks were more often employed in professional and managerial occupations than native-born blacks. While comparisons of studies with different measures and models should be made with care, previous analyses generally lead to the conclusion that if there is a Caribbean advantage, it was greater in 1970 than in 1980, and in 1980, it seemed limited to advantages in the occupational domain.

Using 1990 census data on earnings and occupation, I examine generational differences within this new black minority. Assimilation theory argues that through a process of generational replacement, national origin groups gradually become more similar to the members of the host society (Hirschman 1983). For Caribbean Americans, the assimilation process is more uncertain because if they are losing part of their cultural heritage, the possibility arises that they are identified with the larger black American community (Foner 1985). Cultural assimilation in this context may imply that members of the second generation lose some of the advantages that their immigrant parents had over African Americans, and that their race again becomes a handicap in the status attainment process. In this study, I examine the socioeconomic aspect of the Caribbean American assimilation process by comparing the earnings and occupations of American-born Caribbean men with those of Caribbean immigrant and African American men.

Next to examining generational differences, I contribute to previous research in three ways. First, I update findings of 1970 and 1980 census analyses. Recent data are important because the earnings of native American blacks have deteriorated considerably during the 1980s (Bound & Freeman 1989). The question thus arises whether Caribbean blacks have suffered to the same extent as native blacks, or whether they have been protected from the economic

downturn of the 1980s. Second, I emphasize the heterogeneity of the Caribbean community by examining socioeconomic differences with respect to linguistic group (i.e., Spanish, French, and British-speaking Caribbeans). Does the "black success story" apply to all Caribbean groups, or is it limited, as several authors suggest, to those of British Caribbean descent? Third, I systematically compare differences in occupation and earnings, thus broadening the scope of previous analyses. Are socioeconomic differences in 1990 limited to the occupational domain, or do they also apply to advantages in earnings?

Background

In the past, several authors have tried to explain the socioeconomic success of Caribbean immigrants in the U.S. (Bryce-Laporte 1972; Butcher 1994; Foner 1985; Model 1991; Sowell 1978). These explanations can be grouped in hypotheses focusing on characteristics of the immigrants themselves (supply-side hypotheses), and hypotheses focusing on the way Caribbeans are treated in the American labor market (demand-side hypotheses).

Hypotheses focusing on the supply-side of the labor market argue that Caribbean blacks have a greater motivation for achievement and a stronger work ethic than native-born blacks. Originally, this argument was proposed by Sowell (1978), who attributed differences in work ethic to differences between the American and Caribbean systems of slavery. In a frequently contended essay, Sowell (1978) argued that because slaves in the Caribbean did not experience strong economic competition from a large white lower class, as slaves did in the American south, they had more opportunity for economic initiative and were socialized into a "spirit of capitalism" early on (46). Sowell's argument has been considered provocative because it seemed to imply that a "lack of achievement" orientation, rather than racism or discrimination on the basis of color, is the cause of racial inequality in American society. When we compare the position of West Indian blacks to native whites, however, this implication is disputable. Even if one assumes a greater work ethic on the part of West Indian blacks, one still needs another theory to explain why this has not brought them on a par with whites. Since the West Indian disadvantage vis-á-vis whites is large, Sowell's conclusion that "the West Indian success pattern undermines the explanatory power of current white discrimination as a cause of current black poverty" (49) is exaggerated. In addition, his argument that the position of West Indians in the contemporary U.S. can be traced to differences between the economies of the American South and the Caribbean many generations ago is difficult to prove or to refute, and hence less practical as an explanation.

A more obvious hypothesis about the motivation and work ethic of Caribbean immigrants focuses on differences between American and Caribbean society in modern times. Although many American blacks have entered the middle class in the last decades, structural changes in American society, such as the deteriorating manufacturing industry and the flight of the middle class to the suburbs, have deprived many young urban blacks of successful models for achievement in their community (Wilson 1987). Although most of the Antilles

face serious economic problems as well, blacks have traditionally formed the majority in the Caribbean islands and have occupied a more diverse range of positions in the social hierarchy. The more positive examples of black achievement and the less rigid social classification of racial groups in these societies may well lead to a stronger orientation toward socioeconomic achievement among Caribbean blacks. This argument would apply more to the British Caribbean, where blacks form the majority, than to the Hispanic Caribbean, where they generally constitute a minority.

A second reason why Caribbean immigrants may have a stronger motivation for achievement lies in the process of migration itself. Since people who voluntarily come to the U.S. tend to migrate for economic reasons, they may be specially motivated to perform well in the American economy and may have more talents and abilities that are relevant for socioeconomic achievement than people who do not make the move abroad. Since economically motivated migration is considered to be more selective with respect to economic skills and abilities than politically driven migration (Chiswick 1979), this hypothesis is particularly plausible for immigrants from the English-speaking Caribbean, almost all of whom were motivated by the desire to escape poor domestic economies (Palmer 1974). Because individual data comparing who migrates and who stays behind are scarce, it has been difficult to prove the selective migration hypothesis directly. Indirect evidence for the Caribbean context comes from an old and small-scale study by Tidrick (1971), which shows that students in two Jamaican universities who planned to move to the U.S. were more competitive and more strongly oriented toward economic success than those who planned to stay home, even after considering the influence of class background.

Next to hypotheses focusing on characteristics of the immigrants themselves are arguments focusing on the demand side of the labor market. It has long been argued that the main reason why Caribbean blacks are more successful in the American economy than native born blacks is that they suffer less from racial discrimination by whites (Reid 1939). Some assume that they are favored because of their British accents; others believe they present themselves to prospective or current employers as culturally distinct from, and possibly superior to, native American blacks. These arguments have not been proven systematically, but anecdotal evidence confirms that Caribbeans are perceived as more favorable (Foner 1985). The argument of white favoritism applies more to the English- and French-speaking Caribbean than to the Spanish-speaking Caribbean because the latter may face the risk of double discrimination as blacks and Hispanics in the American labor market.

My study elaborates on earlier analyses of nativity differentials within the black community by comparing Caribbean immigrants to American born blacks with Caribbean ancestry. Both supply- and demand-side hypotheses suggest that second-generation Caribbean blacks would be less successful in terms of achievement than Caribbean immigrants. Second-generation Caribbeans have not experienced a more favorable climate of race relations in the Caribbean, and hence may lack part of the self-confidence that Caribbean immigrants presumably bring with them. In addition, members of the second generation are not selected in the migration process, though they may display some of their

parents' traits. The second generation is also less likely to return if achievements in the U.S. fail to meet expectations.

Demand-side hypotheses imply similar outcomes. The children and grandchildren of Caribbean immigrants have not gone to schools that are heavily based on British or other European traditions, they are probably less likely to be exposed to Caribbean culture, and they may be more likely to speak English fluently or without a British accent. If white employers are less able to distinguish second-generation Caribbean blacks from African Americans, American-born Caribbeans will have less of an advantage over African Americans than Caribbean immigrants.

In summary, an elementary assimilation perspective implies that the children of Caribbean immigrants are becoming more similar to African Americans than their parents. Caribbean blacks thus represent a case where cultural assimilation may hamper rather than improve their socioeconomic achievement. While the scenario of cultural assimilation is plausible in light of what many white national origin groups have experienced in American society (Hirschman 1983), the question of whether Caribbeans lose the cultural distinctiveness that characterized their immigrant parents remains open (Foner 1985). In this study, I address this question by examining the socioeconomic dimension of the Caribbean American assimilation process. I describe income and occupational differences between Caribbean and African Americans, between different generations of Caribbeans, and between different linguistic groups within the Caribbean community. Though census data provide important information on such patterns, they do not allow me to decide between the demand- and supply-side hypotheses directly.

Data

The data I use are the Public Use Microsamples of the 1990 census (U.S. Bureau of the Census 1992). Using the census questions on a person's ancestry and country of birth, I define Caribbean Americans as black immigrants who were born in the Caribbean (first-generation Caribbeans), and American-born blacks who reported Caribbean ancestry (second- and later-generation Caribbeans). African Americans are defined as American-born blacks who did not report a specific ancestry. Of this latter group, 85% answered "black" or "African American" in response to the ancestry question, 3% answered "American," and 12% did not answer the question. That few native-born African Americans report a specific ancestry is plausible given the fact that the vast majority of them have been here for several generations. Because the census dropped the question on foreign parentage after the 1970 census, ancestry data are the only possible way of identifying second and later generation Caribbeans in recent censuses. Lieberson & Santi (1985) have compared classifications on the basis of ancestry and foreign parentage and concluded that inferences regarding educational and economic characteristics were generally similar under the two systems.

African Americans are obtained from a 25% sample of individual records in the 1% microsample. Because of their small numbers, Caribbean Americans are

obtained from the full 5% microsample. The samples I analyze are limited to the noninstitutionalized population, they exclude persons who were born abroad of American parents, and they do not include persons in the U.S. outlying areas. Except for the analyses in Figures 1 and 2, which show the geographical origins and destinations of Caribbean blacks, all my analyses focus on men. For a comparison with women, see Model (1991).

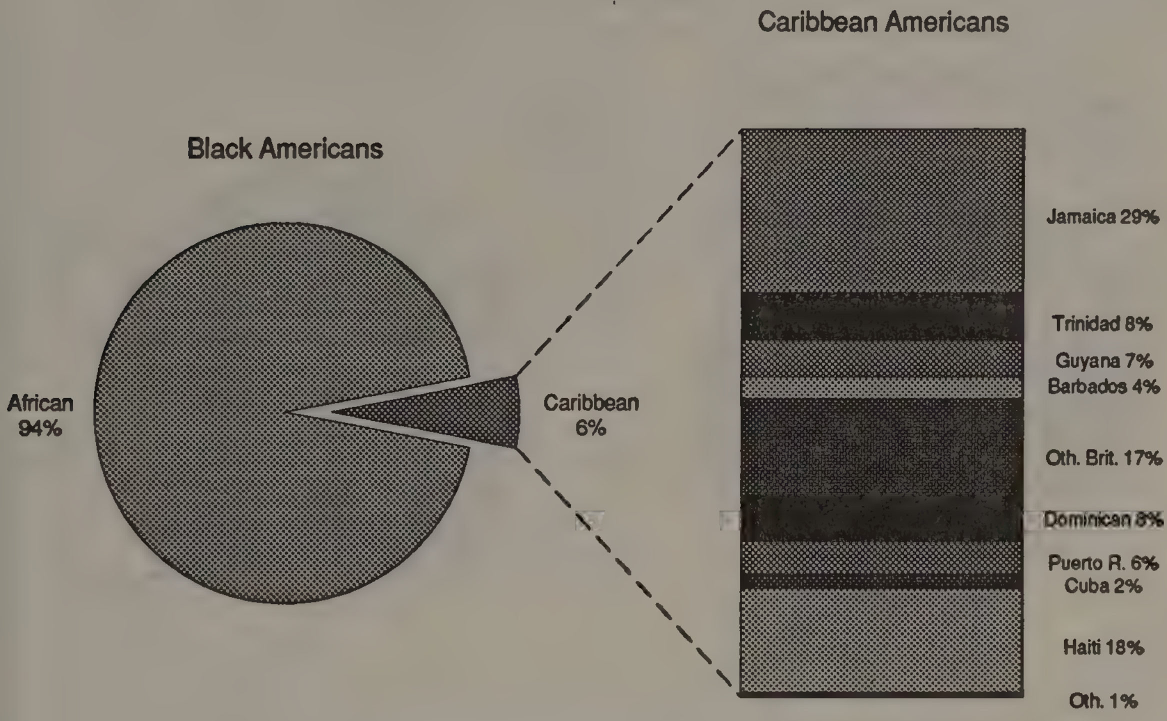
As Figure 1 shows, about 6% of the black community 16 years or older is Caribbean American. Caribbean blacks come from a large number of islands, but a few countries make up the bulk of the immigration flow: Jamaica (29%), Haiti (18%), the Dominican Republic (8%), and Trinidad-Tobago (8%). Considering differences with respect to immigration history and colonial heritage (Reid 1939), the various national origin groups can be classified in three linguistic groups: the English-speaking West Indians (65%), the Spanish-speaking West Indians (16%), and the French-speaking West Indians (19%). Persons are classified based on where they came from or where their ancestors came from, not on the language they themselves speak (which is affected by the assimilation process). The English-speaking Caribbean countries included are Jamaica, Trinidad-Tobago, Guyana, Barbados, Belize, the Bahamas, the Virgin Islands, and a range of smaller islands such as the Cayman and Leeward Islands. The main Spanish-speaking Caribbean countries are the Dominican Republic, Puerto Rico, and Cuba. The French-speaking Caribbean countries are Haiti, Guadeloupe, Martinique, and French Guyana. Note that the term *French West Indian* is often used to refer to Martinique and Guadeloupe, while the population analyzed here is almost exclusively from Haiti. The Dutch-speaking West Indians (Surinam, Curacao, Aruba, Bonaire) are too small of a group in the U.S. to include in the analyses.

As is well known, Caribbean blacks are heavily overrepresented in the Northeast (Figure 2) and concentrated in a few states. About half of them live in New York, 17% in Florida, 7% in New Jersey, and 4% in Massachusetts. More importantly, virtually all of them live in large cities (primarily New York City, Miami, Newark, and Boston). I therefore decided to limit my comparisons to urban blacks. Though uncommon in the literature, the focus on urban blacks is warranted because rural and urban areas have widely different income and opportunity structures. If the aim is to compare groups in fairly similar structural positions, it seems inappropriate to include rural native-born blacks in a comparison with such a highly urbanized ethnic minority.

Differences in Socioeconomic Status

Socioeconomic status is measured by two related indicators, occupational status and hourly earnings. Occupational status is measured by the 1980 version of Duncan's socioeconomic index (SEI) of occupations (Stevens & Cho 1985). Because the 1980 and 1990 occupational classification systems are virtually the same, there were no problems in assigning SEI scores to 1990 census respondents. Earnings are measured by a person's 1989 income from wages, salaries, and self-employment. Because my main interest is in status attainment, not in labor supply, I consider hourly earnings, using information on the number of

FIGURE 1: National Origin of American Blacks 16 Years Old or Older in 1990

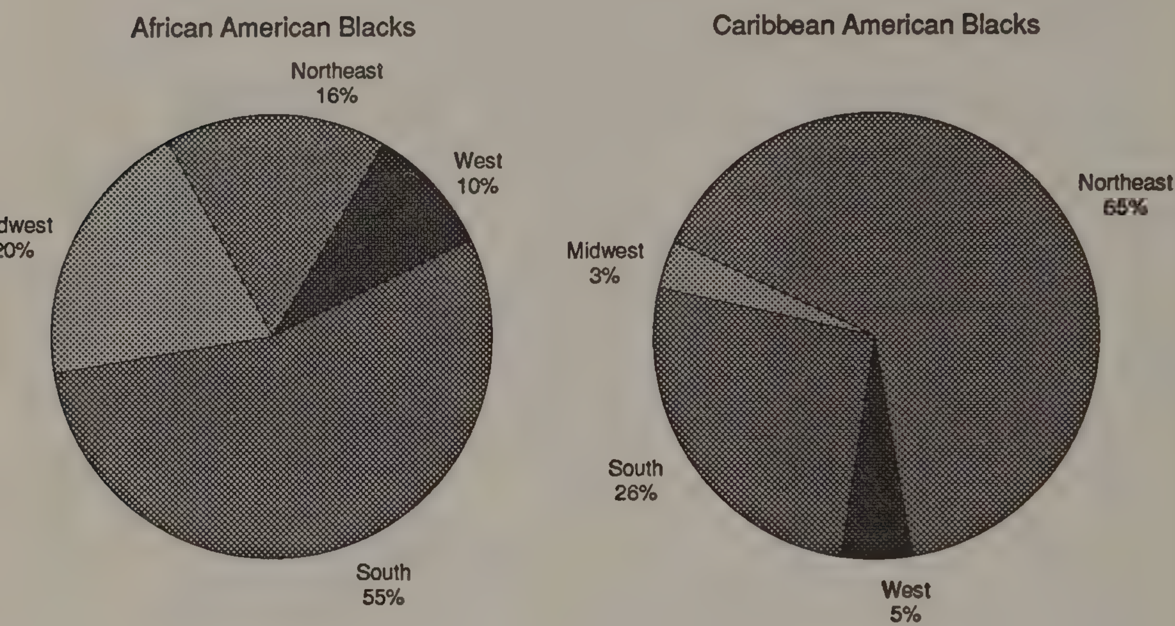


weeks worked in 1989 and the usual number of hours worked per week in that year. Only persons with positive annual earnings are considered.[1]

Since not all men work for pay, the possibility arises that my comparisons are affected by selection bias. Following previous research on black/white differences in earnings (e.g., Bound & Freeman 1989), I therefore limit my analyses and conclusions to a group for whom employment rates are high, that is, out-of-school men who were 25-64 years old at the time of the census. In addition, I use information on "last occupation" for men without a job at the time of the census. For persons who are not working, past occupation is probably the best predictor of the occupation they would have had, had they been in the labor force. Hence, the models of occupational attainment are practically unaffected by possible selection bias.

In the top panel of Table 1, I present data on mean earnings and occupational status for each of the four groups separately (African American, Hispanic Caribbean, French Caribbean, British Caribbean). Because extreme earnings may affect my comparisons, I also present mean logged earnings. Table 1 shows that British Caribbeans have higher earnings than African American blacks. On the other hand, men from the French- and Spanish-speaking Caribbean have lower earnings than African American blacks. It makes little difference here which mean we consider. Differences in occupational status parallel differences in hourly earnings. The British Caribbeans do best, followed by African Americans, Hispanic Caribbeans, and French Caribbeans respectively.

FIGURE 2: Geographical Location of Black Americans



Differences in Background Characteristics

The socioeconomic differences observed in Table 1 may be due to differences in human capital, differences in living arrangement, and differences in geographical location. I therefore estimate regression models to examine subgroup differences in socioeconomic status, net of the influence of such background characteristics. Table 1 (bottom panel) presents the means of the variables included in the regression models.

The first and foremost indicator of human capital is education. I include two measures of schooling: years of schooling completed and attainment of a college degree. Because the 1990 census question on schooling is not phrased in terms of years, as was the practice in earlier censuses, I approximate years of schooling by assigning the number of years it takes to receive the particular grade or degree.[2] I use the attainment of a college degree (B.A., M.A., Ph.D.) as an additional measure to capture possible wage or status premiums for college degrees on top of the benefits a person receives for additional years of schooling. Table 1 shows that on average, British Caribbeans complete slightly more years of schooling than African Americans. When focusing on the top end of the schooling distribution, the difference becomes clearer. The percentage of British Caribbeans who received a college degree is higher than the percentage of African Americans receiving a degree. Men from the Spanish- and French-speaking Caribbean, in contrast, are less educated than both African American and British Caribbean males.

A second human capital indicator is labor market experience and experience squared. Experience is approximated by age minus years of schooling minus 6.

TABLE 1: Means of Dependent and Independent Variables for Out-of-School Urban Black Males Aged 25-64 in 1990

	U.S.-born African American	Spanish-speaking Caribbean	French-speaking Caribbean	British-speaking Caribbean
Hourly earnings (in 1989)	12.41	11.56	11.26	13.64
Logged hourly earnings	2.28	2.16	2.16	2.39
Status of current or last occupation (SEI score)	30.2	28.3	27.7	33.2
Logged SEI score	3.27	3.22	3.18	3.37
Years of schooling	12.0	10.3	10.9	12.1
College degree (percent)	11.2	7.9	12.3	15.5
Years of experience	22.9	24.2	23.2	22.9
Poor English language ability (percent)	.4	31.6	23.0	.9
Married (percent)	49.4	55.5	60.0	64.4
Living in the West (percent)	12.1	4.4	1.8	6.9
Living in the Midwest (percent)	21.5	3.7	2.2	3.7
Living in the Northeast (percent)	17.9	76.6	50.0	63.9
Living in the South (percent)	48.5	15.3	46.0	25.5
Born in the U.S. (percent)	—	16.4	2.7	11.3
Years in U.S. (for immigrants)	—	17.0	12.5	14.7
Unweighted N	8,981	1,977	2,660	7,848

Although this measure captures potential rather than actual experience, it is to be preferred to a model with age and age squared, which does not take into account variations in the duration of schooling (Mincer 1974). Only small differences in experience are observed in Table 1.

A third indicator of human capital is English language ability. Table 1 shows that 32% of Hispanic and 23% of French Caribbeans rate their ability to speak English as poor or nonexistent. In the regression models, I include a dummy variable that takes the value of 1 for those whose language ability is poor (0 otherwise). Because virtually all British Caribbean and African American men have good English language ability, this specification implies that subgroup differences in socioeconomic status apply to men whose English is good.

I further include marital status because earlier studies have found that married men have higher earnings than single men, net of the influence of education and experience. Though part of this difference may be due to selection on the marriage market — highly paid men being more likely to marry — recent empirical studies have suggested that employer favoritism and greater productivity among married men are more important causes of the marital pay advantage (Korenman & Neumark 1991). Table 1 shows that all Caribbean American groups are more likely to be married than African American men. Since this gives them a socioeconomic advantage over African American men, marital status needs to be taken into account in the regression models.

Because a disproportionate number of Caribbean blacks live in New York, New Jersey, Florida, and Massachusetts, and since incomes are generally higher in these areas than, for instance, in the south, where the majority of African Americans lives (Figure 2), I take into account geographical differences by including a set of 4-1 binary variables referring to the region in which a person lives at the time of the census. To further check whether my findings are sensitive to regional differences, I also estimate models for specific regions separately.

Regression Models

CARIBBEAN VERSUS AFRICAN AMERICANS

In Table 2, I present ordinary least squares (OLS) estimates of unstandardized regression coefficients for hourly earnings and occupational status. The first model I consider is defined as follows,

$$\ln Y_i = \beta_0 + \gamma_1 Hisp_i + \gamma_2 Fren_i + \gamma_3 Brit_i + \epsilon_i \qquad \text{(A)}$$

In model A, $Hisp_i$, $Fren_i$, and $Brit_i$ are binary variables that are coded 1 if the individual is in the particular group (0 otherwise). Hence, the effects of these variables can be interpreted as the difference between Caribbean and African American blacks. The variable Y_i refers to occupational status and hourly earnings. Both measures are transformed into natural logarithms to reduce the influence of heteroskedasticity. Although transforming SEI scores to logarithms is uncommon, it facilitates interpretation of the coefficients and allows me to compare effects of a given variable across equations. Both can be regarded as percentage change in the dependent variable.[3]

Model A in Table 2 shows that there are large socioeconomic differences between Caribbeans and African Americans, though the magnitude and direction of these differences depend on which linguistic group we consider. The British Caribbean have a clear advantage over African Americans. For occupational attainment, the coefficient is .089, meaning that they have 9% higher occupational status than African Americans. For hourly earnings, the coefficient is .111, meaning that they have 12% higher earnings. Comparisons with the other two Caribbean groups yields the opposite picture. Compared to African Americans, the French-speaking Caribbean have 5% lower occupational status and 11% lower earnings. The Spanish-speaking Caribbean have 10% lower earnings and equal occupational status. Since no other variables are

included in the model, these results essentially replicate the differences in mean logged earnings observed in Table 1.

To examine whether these differences are due to the influence of human capital, living arrangements, and geographical location, I add a set of $j = 10$ control variables for each individual i,

$$\ln Y_i = \beta_0 + \sum_j \beta_j X_{ij} + \gamma_1 Hisp_i + \gamma_2 Fren_i + \gamma_3 Brit_i + \epsilon_i \quad \text{(B)}$$

In this model, the effects of $Hisp_i$, $Fren_i$, and $Brit_i$ can be interpreted as the difference between Caribbean and African American blacks when holding all other relevant measured characteristics constant.

Model B in Table 2 shows that for British Caribbeans, differences in socioeconomic status net of the influence of background characteristics are smaller than the differences observed in model A. Their occupational advantage over African Americans is reduced to 5% and their earnings advantage is reduced to 1%. When we compare total (model A) and net relative differences (model B), we can conclude that about half of the British occupational advantage and nearly the entire earnings advantage can be attributed to their more favorable background characteristics. That British Caribbeans have a net occupational advantage over African Americans without a corresponding earnings advantage suggests that they have difficulty in translating their occupational advantage into an earnings advantage. Perhaps this is due to a greater emphasis on — relatively poorly paying — high cultural segments of the labor market, such as teaching. That British West Indians have higher-status occupations but similar earnings is consistent with Farley & Allen's analysis of the 1980 census (1989).

For Hispanic and French Caribbeans, controlling for background characteristics changes the socioeconomic disadvantage they have compared to African Americans in a modest fashion. After controlling for the influence of background characteristics, Hispanic Caribbeans have 10% lower hourly earnings than African American males and 2% higher occupational status. Men from the French-speaking West Indies have both lower occupational status (4%) and lower earnings (9%).

Effects of the other independent variables are generally consistent with findings in previous studies of status attainment. Each additional year of schooling is associated with a 3.8% increase in occupational status and a 3.8% increase in hourly earnings. For obtaining a college degree, there is an occupational premium of 62% and an earnings premium of 35% in addition to the benefits of extra years of schooling. There is an increase in earnings for additional years of experience as well, but given the negative effect of the squared term, the rate of this increase declines over the working life.[4] A somewhat unexpected finding is that experience does not affect occupational status. Apparently, black men in the U.S. make monetary gains in careers without corresponding changes in occupation. Also, individuals whose English proficiency is poor or absent have 8% lower occupational status and 15% lower earnings. Married persons have higher earnings and occupational status. The

regional effects show that earnings and occupational status are highest in the Northeast and the West, followed by the Midwest and the South, respectively.

Although the model controls for geographical location, it remains possible that the socioeconomic gap between Caribbean and African American men is different in states where Caribbeans are concentrated. To examine this issue, I estimate model B for Caribbean states (i.e., New York, Massachusetts, and Florida) and non-Caribbean states separately. Subsequently, I test whether the relative socioeconomic advantages differ significantly across these two regions. The results of these comparisons, presented in Table 3, generally show that the relative position of Caribbean Americans is somewhat better in areas where they are not concentrated. The British Caribbean have more of an advantage over African Americans in the non-Caribbean states, and the Hispanic and French Caribbean have somewhat less of a disadvantage over African Americans in those states. These findings are consistent with earlier analyses showing that minority concentration is associated with greater gaps between minority and majority wages (Tienda & Lii 1987). Since these contrasts are not statistically significant, however, no firm conclusions can yet be made about the impact of minority concentration on immigrant earnings, and we may proceed the analysis by focusing on the Caribbean population at large.

GENERATIONAL DIFFERENCES

Are there generational differences within the black Caribbean community? To answer this question, we can compare Caribbean immigrants to native-born blacks of Caribbean ancestry (second and later generation Caribbeans). Comparing immigrants and natives is complicated by the fact that immigrants typically face some disadvantages in the labor market upon arrival in American society due to a lack of information on jobs and possibly a shortage of social capital to support the status attainment process as well. The longer they have been in the U.S., the more they overcome such problems, and at some point, they tend to reach socioeconomic parity with natives (Chiswick 1979; Chiswick & Sullivan 1995). Because assimilation may occur during an immigrant's lifetime, and not only between generations, we need to compare American born Caribbeans to Caribbean immigrants who have been in the U.S. for different periods of time.

To make these comparisons, I estimate the following regression model.

$$\begin{aligned}\ln Y_i = \beta_0 &+ \gamma_1 Hisp_i + \gamma_2 Fren_i + \gamma_3 Brit_i \\ &+ \gamma_4 Hisp_i x Imm_i + \gamma_5 Fren_i x Imm_i + \gamma_6 Brit_i x Imm_i \\ &+ \gamma_7 Hisp_i\, x\, Imm_i\, x\, Dur_i + \gamma_8 Fren_i\, x\, Imm_i\, x\, Dur_i + \gamma_9 Brit_i\, x\, Imm_i\, x\, Dur_i \\ &+ \epsilon_i\end{aligned} \tag{B}$$

In model B, Imm_i is coded 1 for immigrants (0 otherwise) and Dur_i is the number of years immigrants have been in the U.S., scaled in decades (0 for all other groups). Due to the specification of interaction effects chosen in model B, each parameter has a meaningful interpretation: γ_1 through γ_3 give the difference between native-born Caribbeans and African Americans; γ_4 through γ_6 give the difference between native-born Caribbeans and Caribbean immigrants upon arrival in the U.S.; γ_7 through γ_9 give the increase in earnings or

occupational status among immigrants for each ten years of duration in the U.S.[5] Estimates of model B appear in Table 3. For the sake of presentation, I do not report effects of the other independent variables in the equation.

Effects of duration of stay in a cross-sectional dataset of immigrants should be interpreted with some caution. Borjas (1985) has shown that the socioeconomic potential or "quality" of more recent immigrant cohorts is lower than that of immigrant cohorts who entered many decades ago, a phenomenon he attributes to changes in the 1965 Amendments to the 1952 Immigration and Nationality Act. Because duration of stay and year of immigration are by definition perfectly (negatively) correlated in a cross-section, assimilation during the life of an immigrant as inferred from cross-sectional analyses may in fact reflect a secular decline in the socioeconomic potential of entering immigrants (i.e., immigrant cohorts). There are several reasons, however, why an analysis of duration effects is still valuable in the present context. First, Borjas's argument applies more to the changing national origin mix of immigrants than to changes in the socioeconomic potential of specific national origin groups,

which is the issue examined here. Second, Borjas has shown that even when immigration cohort effects are removed, large effects of assimilation remain. Third, an important aspect of the socioeconomic potential of immigrants, i.e., educational attainment, is included in the model. It is somewhat difficult to imagine that there will be a decline in the socioeconomic potential across immigrant cohorts once educational attainment is controlled for. Fourth, in an analysis of cohort and duration effects for various national origin groups, Borjas (1987) has shown that for several of the sending countries considered here (e.g., Jamaica, Trinidad, Haiti, Cuba, with the exception of the Dominican Republic), there is no statistically significant decline in the socioeconomic potential of entering immigrants. Hence, the duration effects estimated in Table 4 will largely reflect assimilation during the life course of an immigrant.

The effects of the immigrant interactions in Table 4 are negative and generally statistically significant, indicating that natives have higher occupational status and earnings than immigrants who just arrived in the U.S. For example, in the occupational status equation, the effect for British immigrants is -.065, showing that immigrants have 6% lower occupational status than natives with similar amounts of education and experience. We further notice that all duration effects are positive, and generally statistically significant as well. Hence, immigrants gain status the longer they have been in the U.S. For British immigrants, the effect on occupational status is .028, indicating that they gain about 3% per decade. In general, we observe that assimilation occurs slower for British Caribbean immigrants than for the other Caribbean immigrants, probably because their human capital skills are more easily transferrable to the American labor market.

Although Caribbean natives are doing better than Caribbean immigrants who just arrived in the U.S., the question remains whether they are also doing better than immigrants who have been in the U.S. for longer periods of time. To answer this question, I use the model in Table 4 to make comparisons with immigrant Caribbeans at different periods of stay (5 years, 15 years, and 25 years).[6] These calculations show that even though Caribbean immigrants improve their position during their life in the U.S., at most of the relevant durations, they are still surpassed by native Caribbeans (Table 5). We can also compare native Caribbeans to the "average" Caribbean immigrant, that is, immigrants who have been in the U.S. for the average duration of the particular immigrant group. This comparison yields a similar pattern, though the generational advantage is clearly greater for French and Hispanic Caribbeans than for British Caribbeans. Hence, we can conclude that native Caribbeans have higher socioeconomic status than most immigrants, and that they are comparable to immigrants who have been in the U.S. for quite a long period of time. This pattern of assimilation is similar to what many white ethnic groups experienced in the U.S. (Hirschman 1983).

The final question is how immigrants and natives compare to the African American community. To answer this question we focus on native-born Caribbeans first. Table 4 shows that the main effects of language group (γ_1, γ_2, and γ_3) are generally positive, suggesting that native Caribbeans have higher earnings and occupations than African Americans. However, this effect is only significant for British Caribbeans, and for them, it is limited to the occupational

domain. On average, British Caribbean natives have 7% higher occupational status than African Americans.

As shown before, immigrants have lower status than native Caribbeans, but they reach parity after a certain number of years in the U.S. At which point do Caribbean immigrants reach parity with African Americans? Simple algebraic manipulations of the equation in model B show that this point is reached when $Dur_i = -(\gamma_1 + \gamma_4)/\gamma_7$.[7] The point at which British Caribbeans immigrants begin to have an earnings advantage over African Americans is reached soon after they arrive (12 years). Their occupational advantage is already present when they arrive. For the other language groups, the picture is different. Immigrants from the Spanish- and French-speaking West Indies generally take much longer before they begin to have an advantage over African Americans (34 and 21 years for earnings, and 15 and 19 years for occupational status).

Conclusion

In the 1990s, there continue to be socioeconomic differences between Caribbean American blacks on the one hand, and African American urban men on the other but the results differ strongly by linguistic group. Both native British Caribbeans and British Caribbean immigrants who have been in the U.S. for more than a short period of time are doing better than African American blacks.

Though this result is consistent with the stereotype of Caribbeans as a "black success story" in American society, the British advantage is limited to the occupational domain and is not as spectacular in magnitude as is commonly believed. The advantage is not large enough, for example, to bring them on a par with white men (Bound & Freeman 1989). The picture is different for Caribbean blacks from the Spanish- and French-speaking West Indies. Here, immigrants are worse off than African Americans for most of their life in the U.S. After a long period of stay in the U.S., they eventually reach parity with their African Americans peers. Similarly, native-born Hispanic and French Caribbeans are not significantly different from the African American community.

That differences are language-specific is consistent with hypotheses about demand and supply factors. Supply-side hypotheses argue that Caribbeans have a greater motivation for achievement than native-born African Americans. Such differences can be attributed to selective migration on the one hand, and to socialization in black majority societies on the other. British Caribbeans tend to migrate for economic reasons, while Haitians migrate for political reasons. Despite the high social and emotional costs involved, political immigration or other forms of coerced immigration are generally believed to be less selective with respect to occupational ability than economically driven immigration. In addition, the British Caribbeans generally have black majorities while the French and the Hispanic West Indies considered here do not. Hence, the British may be more oriented towards achievement because they have been socialized in societies with black majorities and relatively successful economic role models among their peers. Support for demand-side hypotheses can be found as well. Hispanic West Indian blacks, for example, may face double discrimination because they are both black and Hispanic. Unlike the British, they do not combine their race with a more favorably looked upon British heritage.

Generational differences within this new black minority were found as well. On average, Caribbean blacks who were born in the U.S. have higher earnings and occupational status than Caribbean immigrants upon arrival. Immigrants reach parity with natives after several years in the U.S., but the point at which this occurs is in most cases well above the average number of years that Caribbean immigrants have been in the U.S. For British Caribbeans, this implies that the second and later generations have a somewhat greater advantage over African Americans than the first generation. This result does not support the notion suggested by assimilation theory that later generations lose the "immigrant" advantage that their parents had, and consequently reach parity with African Americans.

Several reasons can be suggested to explain this exception. First, cultural assimilation may be mitigated by the influence that immigrants have on their children. More specifically, Caribbean immigrants may transmit their orientation toward hard work and achievement by emphasizing the importance of schooling for their children. They may be particularly motivated to transmit such values if they contrast their own experiences in the U.S. with those of African Americans in their surroundings. Second, even though American-born Caribbean blacks were never faced with the decision of whether to migrate, the talents and abilities on which their parents are "selected" can be passed on to

later generations through the socialization process (Chiswick 1977). Third, intergenerational influences may be amplified and reinforced by geographical segregation between Caribbean and African Americans. Though there is some evidence pointing in this direction (Denton & Massey 1989), more research is needed to examine patterns of segregation between the two black communities.

Notes

1. Hourly earnings of $100 and more are recoded to 100.

2. The coding is done as follows: no school, nursery school and kindergarten (0 years), 1st-4th grade (2.5 years), 5th-8th grade (6.5 years), 9th grade (9 years), 10th grade (10 years), 11th grade (11 years), 12th grade and high school graduates (12 years), some college without degree and associate college degree in occupational program (13 years), associate college degree in academic program (14.5 years), Bachelor's degree (16 years), Master's degree (18 years), professional and doctorate degree (22 years).

3. For continuous independent variables, the percentage change in the dependent variable is given by $100 \times ß$; for binary independent variables, the percentage difference in the dependent variable between subgroups is given by $100 \times [\exp(ß)-1]$.

4. The point at which log earnings actually begin to decline with experience can be found by setting the derivative of equation B with respect to experience to 0 and rearranging terms. This yields $(-1 \times .249)/(2 \times -.028) = 4.4$ which amounts to 44 years of experience.

5. I also tested nonlinear duration effects using duration and duration squared but generally found no significant improvement of the models.

6. The model also allows one to compute at which point the socioeconomic status positions of immigrant and native Caribbeans are equal. For example, according to model B, the (logged) earnings of Hispanic Caribbean immigrants are: $ß_0 + \Sigma_j ß_j X_{ij} + \gamma_1 + \gamma_4 + \gamma_7 Dur_i$. The (logged) earnings of Hispanic Caribbean natives are: $ß_0 + \Sigma_j ß_j X_{ij} + \gamma_1$. Hence, the earnings of Hispanic immigrants and natives are equal when $Dur_i = -\gamma_4/\gamma_7$.

7. According to model B, the (log) earnings of Hispanic Caribbean immigrants are: $ß_0 + \Sigma_j ß_j X_{ij} + \gamma_1 + \gamma_4 + \gamma_7 Dur_i$. The (log) earnings of African Americans are: $ß_0 + \Sigma_j ß_j x_{ij}$. Hence, the earnings of Hispanic immigrants and African Americans are equal when $Dur_i = -(\gamma_1+\gamma_4)/\gamma_7$.

Deprivation and Race Riots: An Extension of Spilerman's Analysis*

SUSAN OLZAK, *Stanford University*
SUZANNE SHANAHAN, *University College Dublin*

Abstract

Many scholars currently link the growth of a black underclass to the persistence of racial tensions and riots in American cities. However, nearly all previous systematic studies of race riots refute these claims. We propose an alternative explanation that rests on competition processes. In this article we extend Spilerman's 1971 analysis of community characteristics and race riots to include 1954-93. Our results parallel earlier ones that found little evidence that black poverty or racial disparities in income, education, and occupation caused race riots. Furthermore, we find that the effects of black poverty are generally opposite from what most deprivation theories would lead us to expect. Both low income for blacks and dilapidated housing significantly depress the rate of racial unrest. Finally, we find that competition that is expressed as the contraction of job opportunities for minorities created by demographic pressures and unemployment significantly increases the rate of race riots.

For decades social scientists were convinced that disparities between races in economic opportunity generated racial unrest (Blauner 1971; Chicago Commission on Race Relations 1922; Downes 1969; Grimshaw 1960; Lee & Humphrey 1943; Morgan & Clark 1973; Myrdal 1944; U.S. National Advisory Commission on Civil Disorders 1968). The majority of systematic studies on race riots during the 1960s found little support for a causal connection. Regardless of the more recent findings, such ideas continue to influence public perceptions of the causes of riots (e.g., *The Economist* 1992).

** Preparation of this article was supported by a grant to the first author from the National Science Foundation (SES-9196229). Expert research assistance and suggestions were provided by members of the Ethnic Collective Action Workshop at Stanford University: Andy Almazan, Lisa Brooke, Mateo Cordova, Sergio Garza, Angela Jones, Amy Lanigan, Ruth Lopez, Adam Miller, and Barry McMillon. We would like to extend our appreciation to Seymour Spilerman, who graciously sent us his original data on community characteristics. Finally, colleagues Michael Hannan, Elizabeth H. McEneaney, John Meyer, Daniel Myers, and William Tobin offered extremely useful criticisms and suggestions on previous drafts of this article.* *Direct all correspondence to Susan Olzak, Department of Sociology, McClatchy Hall, Stanford University, Stanford, California 94305.*

 Social Forces, March 1996, 74(3):931-961

It is intriguing that explanations of unrest by means of poverty have survived despite the overwhelming number of studies that contradict them (e.g., Bloombaum 1968; Lieberson & Silverman 1965; Spilerman 1970b, 1971, 1976). Although black poverty is widespread in urban settings, deprivation levels apparently do not distinguish between riot and nonriot cities (e.g., Bloombaum 1968; Spilerman 1970a). Nor does a widening gap in income or occupational prestige predict riot severity (Spilerman 1976). Nevertheless, grievance and poverty models of unrest became the standard explanation for race riots located in black ghettos (Boskin 1976; Feagin & Hahn 1973).

Recent outbreaks of racial violence (e.g., in south central Los Angeles or Liberty City in Miami) have stirred renewed interest in deprivation explanations. Because these race riots occurred in minority communities with high rates of unemployment, widespread poverty, and poor housing, deprivation explanations seem pertinent to many observers. To date, no cohesive argument has been offered that is consistent with both prior findings and current examples of racial unrest.

In this article we examine an alternative to deprivation theory that is based upon collective action perspectives. We examine the effects of both competition processes and the changing urban conditions of poverty, occupational segregation, and the shrinking stock of housing for low-income minorities. We also offer analysis of new data on race riots in cities from 1954 to 1993, so we can assess the generalizability of previous findings. Our research analyzes the rate of race riots across 204 of the cities with the largest populations in four decades of American race relations.

The empirical analysis that follows highlights one implication of the competition perspective of ethnic collective action — that changes in the size of the minority population and economic contraction together spark ethnic/racial conflicts. To address this point, our analysis uses information on urban poverty, city political structure, and economic indicators in models of racial unrest in cities. In conducting this research we were fortunate to have access to Spilerman's original data on poverty and political characteristics from 1950 to 1960 at the city level. In this article we combine Spilerman's information on urban poverty, population composition and change, and political structure with original data collected on racial unrest.[1]

Defining Ethnic/ Racial Collective Action

Previous research on ethnic collective action has distinguished between two broad categories of events: race/ethnic protests and race and ethnic conflicts (Olzak 1992). Ethnic protests are public, collective events in which an ethnic group makes a claim or articulates a grievance on the basis of ethnic or national identity. The claim is specifically ethnic and is made on behalf of the ethnic group as a whole. Protests are usually on behalf of one group, which is making a request to change racial policies, or to register a grievance, as in claims of police brutality. Most protests are also distinguished by the fact that violence may occur but it is usually not instigated by the protestors themselves. The civil-rights protest is a modern prototype of an ethnic protest.

The second broad category is ethnic conflicts, in which two or more ethnic groups are engaged in a collective confrontation with each other, or an ethnic group attacks a specific group as a symbol of authority or law, such as the police or National Guard. Activity usually involves an attack on group members (or an institution symbolizing that group, such as a synagogue) based solely on the ethnic or racial identity of the group. Graffiti or epithets or insults will be used to denigrate another group's language, skin color, or nationality. Conflicts may, but do not necessarily, involve violence or the threat of violence to people or property. Ethnic conflicts are distinguished from protests by the presence (real or symbolic) of an ethnic target of the event and the presence of a threat or actual use of violence to attack a group. Using these definitions of ethnic collective action, it becomes clear that large-scale riots could emerge during the course of either protests or conflicts.

The possibility that protests or conflicts could lead to rioting prompts a new question: How are race riots different from racial protests and conflicts? The answer to this question is not straightforward. This is partly because race/ethnic violence has taken many forms in many settings, in many countries and partly because riots can involve more than one race or ethnic population.[2] Another complication documented in previous research on racial unrest is that racial violence instigated by different race/ethnic groups reveals very different causal patterns (Olzak 1992; Tolnay & Beck 1995). Finally, there are important considerations of maximizing comparability across studies. For example, Lieberson and Silverman (1965), Spilerman (1970b, 1971, 1976), and Wanderer (1969) analyzed instances only of black race riots. We find this last issue to be a compelling one and so we follow these researchers and restrict our definition of race riots to spontaneous, large-scale, and public displays of racial violence where there was property damage, injuries, or deaths. Further, to ensure comparability with earlier research on American race riots, we restrict our analysis to events in which blacks initiated acts of aggression against property, persons, or symbols (Spilerman 1970a:630).

Collective Action Perspectives and Race Riots

ABSOLUTE AND RELATIVE DEPRIVATION PERSPECTIVES

Two branches of deprivation theory have informed the study of race riots. According to absolute deprivation formulations, cities where high proportions of blacks have low levels of education or are employed in highly segregated and low-paying jobs are more likely to experience racial unrest (Chicago Commission on Race Relations 1922; Park 1949; U.S. National Advisory Commission on Civil Disorder 1968). According to this view, the dramatic rise of race riots in Newark, Chicago, Detroit, and other cities during the mid-1960s seemed to provide strong confirmation of these theories.

Deprivation theories of racial unrest have reemerged in the literature on the urban underclass and unrest. Recent analyses of the construction of black ghettos suggest that black poverty has become widespread at the same time that racial tensions remain high (Harris & Wilkins 1988; Massey & Denton 1993). In this view, the concentration of poor families in communities where African

Americans and other poor minorities have been segregated encourages racial grievances that sporadically erupt into episodes of fire bombing, looting, or armed violence. For example, Massey and Denton (1993), observe

> The economic deprivation, social isolation, and psychological alienation produced by decades of segregation bore bitter fruit in a series of violent urban riots during the 1960s. The violence began in Birmingham, Alabama, in the summer of 1963, but the real bellwether was the Los Angeles riot of August 1965, which did $35 million worth of damage and left 4,000 injured and 34 dead. After sporadic violence in Chicago and Cleveland during the summer of 1966, a convulsive wave of mob violence erupted during July and August of 1967, when black ghettos in sixty U.S. cities exploded in a cataclysm of frustration and rage. (58)

Eisinger (1973), Graham and Gurr (1969), Gurr (1972), and others offer a revised version of deprivation theory to explain why racial unrest occurs during periods in which minorities are becoming less deprived. This related line of argument emphasizes that relative disparities in education, income, and occupations for whites and blacks ignite unrest. One popular version of the relative deprivation argument holds that racial unrest arises when the black/white gap in attainment grows at the same time that minority expectations are rising. Political scientists such as Gurr and Eisinger emphasize that grievances are fundamentally political, driven by the lack of political power and absence of local control over city government and services in minority communities. In contrast, sociologists tend to emphasize poverty and unemployment as key structural features of racial discrimination leading to unrest (e.g., see Coser 1972).

LIMITATIONS OF DEPRIVATION THEORIES

Advocates of deprivation theories have met criticism from several sources who contend that deprivation theories have failed to offer a mechanism linking deprivation, grievances, and the inclination to participate in riots (Keily & Isaac 1984). Others are doubtful because race riots peaked during a period in which average levels of income (by educational levels) for blacks were approaching those of whites (Wilson 1978). The trajectories of these two temporal processes are inconsistent with deprivation theory expectations.

In general, deprivation theories have not fared well in most systematic empirical investigations of the topic. In particular, few researchers find evidence that underclass poverty was associated with participation in riots (Paige 1971; Spilerman 1970a, 1971). Researchers find that cities with less black poverty experience higher rates of race riots than do cities with higher proportions of blacks in poverty. Concentration of poverty in minority populations does not appear to lead to protest against such conditions (Spilerman 1970a, 1971, 1976). Moreover, it appears that integration in housing and occupations increases racial violence under some conditions (Grimshaw 1969; Wilson 1987).

Deprivation explanations of racial unrest in general are often limited by a reliance on case studies. Deprivation explanations evoke powerful images that can describe how racial injustice accumulates to reach intolerable levels, but attributing cause to descriptions of conditions in riot cities is problematic because such descriptions ignore what conditions may hold in cities without riots (Spilerman 1970b). Most case studies that emphasize racial poverty suffer

from selection bias in that they are based on cities that experienced riots (e.g., Ladner et al. 1981). This type of analysis describes the preconditions in a riot city but cannot explain the process.

Other researchers investigating causal factors have surveyed riot participants after outbreaks of racial violence. (See Oliver & Johnson 1984; Paige 1971.) Establishing a causal link between reports of grievances and outbreaks of violence *after* a riot has proven difficult. One could easily imagine the reverse causal sequence, in which rioting sharpens the focus of poverty conditions into political grievances (Piven & Cloward 1977).

Although deprivation theories are flawed, they continue to affect public policy, academic debate, and public opinion on the causes of race riots. More than twenty years have elapsed since most of the key studies of race riots at the local level were published.[3] So it seems to be an opportune time to reinvestigate deprivation explanations of racial unrest. Since these studies were published, new developments in collective action theory and methods have proved useful to the study of collective unrest. (See McAdam, McCarthy & Zald 1988 and Olzak 1989 for reviews.) In the following section we apply some of these perspectives to examine deprivation arguments through the lens of collective action theory to provide some new insights into the causes of racial unrest in the contemporary period.

RESOURCE MOBILIZATION THEORY AND RACIAL UNREST

Several variants of resource mobilization theory emerged partly to fill the gap created by the empirical failure of deprivation perspectives (Tilly 1978). In particular, resource mobilization and competition theories suggest that declining (rather than growing) inequality facilitates higher rates of mobilization (Blalock 1967; Jenkins 1983; Tilly 1978). The resource mobilization perspective draws attention to processes of social change that redirect resources away from powerful groups to more disadvantaged ones. By this argument, under conditions of rising resources and declining disadvantage, solidarity and mobilization by the powerless or challenger groups is encouraged.

Using resource mobilization perspectives to analyze social protest has been useful in identifying forces of change that facilitate collective action. The prevailing view from leading theories of collective action would lead one to expect that protest activity in particular occurs during periods of economic expansion rather than deprivation. If we follow Baldassare (1994), Harris and Wilkins (1988), Rossi (1973), and others who consider race riots broadly as a form of racial protest, then theories of racial protest become relevant to this study of racial unrest. In particular, Morris (1984) successfully applied a version of resource and organizational theories to racial protest. He demonstrated that indigenous resources within the black community (notably student and religious organizations) that were mobilized by African Americans became channeled into a variety of protest movement organizations.

Recent reviews of collective action theory underscore the importance of many of the insights drawn from resource mobilization theorists. Resource mobilization theorists focus on the dynamics of organizational growth and decline in social movements and movement activity (McCarthy, McAdam &

Zald 1988). Such an emphasis has been a welcome shift away from static models and conditions of poverty or emotional states of deprivation.

Although they are extremely informative, resource mobilization theories do not directly address the question of why improving conditions would produce racial unrest rather than mobilization along class, occupation, gender, or some other boundary. To answer this question, we combine aspects of resource mobilization theories with competition perspectives of race relations to explain the conditions under which minorities or disadvantaged groups mobilize racial protest, conflict, and rioting.

COMPETITION PERSPECTIVES AND RACIAL UNREST

Until recently competition theories have focussed on instances of racial and ethnic unrest in which the advantaged groups attack minorities to contain or restrict competition (Blalock 1957, 1967; Bonacich 1972; Olzak 1992; Spilerman 1970a). This article shifts the focus of competition theory to consider the question of whether competition fuels collective action by the disadvantaged as well.

Competition theories of race relations build on Barth's (1969) insight that displacement and exclusion are generated by competition. It assumes that initial overlap of habitats intensifies competition among groups, which in turn encourages attempts to exclude the competitors. Such attempts at exclusion often entail violent conflict.[4] Competition theories treat race or ethnicity as a *social boundary*, commonly based upon characteristics such as geographical origin, race, religion, language, or some other cultural symbol. Which (if any) racial or ethnic markers become emphasized depends upon the context of interaction (Barth 1969). Race riots are considered here as an extreme form of ethnic collective action, in which large-scale violence and public confrontations based upon racial grievances become widespread.

The ecological tradition focuses on competition as a key social process that activates and deactivates ethnic identities and boundaries. Competition shapes collective action organized around ethnic boundaries, and ethnic collective action in turn affects the persistence and salience of ethnic boundaries (Olzak & West 1991).[5] We follow Blalock (1967), who defines ethnic competition as

> involving the idea that two or more individuals are striving for the same scarce objectives, so that the success of one implies a reduced probability that others will also attain their goal. (73)

One important implication of this view is that competitors do not need to be aware of each other's existence. Nor does the tradition assume that competition inevitably produces conflict and strife. Instead, the theories specify that the rate of ethnic conflict depends on the degree of niche overlap. Barth (1969) develops this point in distinguishing the conditions that determine stable versus unstable ethnic relations:

> Stable inter-ethnic relations presuppose such a structuring of interaction: a set of prescriptions governing situations of contact. . . . [but] when two or more interspersed groups are in fact in at least partial competition within the same niche . . . one would

expect one such group to displace the other, or an accommodation involving an increasing complementarity and interdependence to develop. (16-20)

Competition theorists maintain that the likelihood of racial and ethnic conflict is low when ethnic and racial groups occupy nonoverlapping (or segregated) regions of social structure (Barth 1969; Olzak 1992). An increase in niche overlap has important consequences for conflict: when groups come to occupy the same niche, the historically more powerful or advantaged group attempts to exclude competitors. When the less powerful resist these attempts, racial conflict and violence ensues.

Competition perspectives add that forces that break down racial barriers also encourage racial competition among formerly segregated groups. If breakdown of racial segregation is accompanied by decreasing racial inequality, then mobilization by disadvantaged groups is likely to occur. Thus both resource mobilization and competition theories of ethnic mobilization hold that competition forces could have two consequences: It can generate waves of unruly protest (on the part of disadvantaged minorities) in the form of race riots or rising competitive forces can cause reactive mobilization on the part of dominant groups. (And the two can be mutually reinforcing, as in movements and countermovements.)

What kinds of changes would produce more racial competition? Economists and economic historians generally argue that tight markets imply that overall labor market competition is intensifying when there are signs that the economy is becoming weak (compared to periods of growth or recovery — Higgs 1977). For race/ethnic groups, a rise in minority unemployment rates would signal a downturn in their fortunes (Jencks & Peterson 1991). To the extent that recessions and depressions increase pressure to find jobs that are less plentiful, competition among minorities in the same job niche increases. Economic contraction may also force those with middle-level jobs to search for unskilled jobs, thus pitting older, upwardly mobile cohorts against each other — or perhaps competition with earlier waves of immigrants or migrants increases (Wilson 1978). Factors that indicate a downturn in the economy are therefore expected to produce ethnic collective action in response to a shrinking job market. By this argument, we would expect that unemployment generates higher levels of collective violence instigated by minorities.

Competition theories, including split labor market formulations, further specify the relationship by emphasizing that it is not job segregation and economic hardship per se that activates ethnic antagonism (Bonacich 1972). Rather, ethnic antagonism is due to economic factors that raise the supply of low-wage labor. This in turn increases competition among ethnic groups (Blalock 1957, 1967). In retaliation, groups affected by hardship direct attacks against the group believed to be the source of that competition. To the extent that the disadvantaged resist becoming victimized, racial unrest escalates.

One implication of the split labor market formulation is that the combination of a rising supply of ethnic/racial labor willing to work at lower than prevailing wages and economic contraction intensifies ethnic competition.[6] That is, these formulations imply an interaction effect between a declining set of job opportunities and immigration affecting the rate of ethnic collective action. Thus

competition theories contrast with economic hardship formulations in arguing that economic decline does not inevitably aggravate ethnic relations. Rather, they argue that unemployment, in combination with high proportions of minorities, raises levels of ethnic competition, which in turn increases rates of ethnic collective action, at least initially.

Our overall argument holds that competition elevates ethnic tensions under two similar conditions of rising competition. The first condition would be one of general elevation of competition in the labor market as a whole: when population increases at the same time that unemployment rises, ethnic competition rises overall. In the second, economic contraction within the minority niche would reduce the number of jobs open to immigrants, minorities, and other less-skilled workers, raising the level of competition for fewer openings in low-paying jobs. To the extent that the minority population in particular rises, competition involving minorities would be intensified when these conditions hold because demands for jobs and housing in minority communities would be increasing at the same time that resources for this group would be shrinking.

Thus the main goal of this article is to evaluate the usefulness of a competition explanation of racial unrest. In doing so we attempt to reconcile the assumptions of poverty and deprivation theories with past research findings.

Research Design and Measurement

Our research analyzes the count of race riots that occurred in any one of 204 largest population cities in the U.S. from 1954 to 1993. The 204 cities represent all cities for which full data on events, poverty, population composition, and political structure exist.[7]

TIME FRAME

We add to Spilerman's research on race riots (which reported analysis of the 1961-68 period) by beginning our observations in 1954 and then extending our analysis into the 1990s. While only a few riots occurred before 1961, we begin our observations on racial unrest in 1954, which marks an important institutional shift in American race relations: it marks the year of the landmark Supreme Court decision, *Brown* v. *Board of Education of Topeka,* mandating that all public schools begin to desegregate "with all deliberate speed." Our data include initial reactions to this ruling, some of the first civil-rights movement activities in the early 1950s, racial unrest in urban centers during the 1960s, and other race/ethnic confrontations (including the 1992 Los Angeles race riot).

NEWSPAPER SOURCES

Our research design tracks histories of all instances of civil disorders that met our criteria and were reported in the *New York Times.*[8] We first identified "candidate events" from the NYT Index and then coded characteristics of race riots from daily microfilm accounts. Our coding scheme judges that a race riot occurred if the event involved racial grievances against discrimination or perceived racial injustice and in which 30 or more persons engaged in violent

activity that lasted several hours. In our coding scheme, the distinguishing feature of race riots was the articulation of racial grievances voiced by the participants, but this is not the sole characteristic of race riots. In most (but not all) cases, substantial violence occurs, often involving some combination of injuries, looting, arson, sniping, and damage to property.[9] In all cases, the police were present in large numbers. We reasoned that because racial deprivation theories assume that gaps between the economic conditions of races drive unrest, it made sense to focus on poverty characteristics and race riots within the same community. Here we analyze race riots in which African Americans were the main participants.

Daily reports from the *New York Times (NYT)* are collected in two stages. We first identified "candidate events" from the *NYT* Index, determined whether they fell under our coding criterion, and then coded characteristics of events from microfilms of daily accounts. Following an established tradition in collective action research, the research project used newspaper accounts coded from daily microfilms of the *New York Times* to provide continuous coverage of events in cities.[10] Several empirical investigations of possible sources of bias have shown convincingly that national newspaper accounts have less reporting bias than local accounts, contrary to original suspicions (Snyder & Kelly 1977). On the other hand, systematic comparisons of newspaper accounts to official statistics (using records of police permits) show that newspapers are likely to be influenced by the size of protests (McCarthy, McPhail & Smith n.d.).

More recently, Olzak and Brooke (1995) compared more than twenty riot accounts in the *New York Times* to those found in several local newspapers and in one aggregated newspaper data bank.[11] Because of findings in earlier studies, these authors thought it prudent to consider the possibility that local sources differ from *New York Times* accounts in systematic ways. They compared accounts of events (or nonevents) in Detroit, Chicago, Miami, and Atlanta in local sources with accounts in the *New York Times*. They also compared two local black newspapers with local mainstream presses. Their comparison of local, regional, and *New York Times* accounts of race riots found surprisingly few discrepancies that matter to event-history analysis. No major differences among the *Atlanta Constitution, Miami Herald,* and the *New York Times* were found for key variables of the timing, duration, number, and ethnicity of those involved or the location of riots. There were some discrepancies in arrest records and estimates of police presence, but these did not vary by more than 10% (which can be attributed to the timing of newspaper deadlines in combination with time zone differences).

INDEPENDENT VARIABLES

We analyze the effects of all independent variables at the city level provided by Spilerman in his original analysis of racial disturbances (Spilerman 1970a). The political structure measures and black occupation, education, and income variables are from Aiken and Alford (1970). A complete set of these variables is available for 204 U.S. cities. All indicators are from the 1960 census with the exception of dilapidated housing, which is available only for 1950, the change

in nonwhite population from 1950 to 1960, and the change in total population from 1950 to 1960.[12]

INDICATORS OF SOCIAL DISORGANIZATION

As noted in Spilerman (1970a, 1971), social disorganization arguments hold that in-migration of minorities and rapid population growth induce strain on resources and ethnic tensions among new residents. Furthermore, a higher percentage of unlivable housing units puts a strain on city resources, constituting a major grievance for the poorest minority residents (Wilson 1987). According to the disorganization perspective, all three indicators would produce higher levels of racial unrest.

Three measures of community disorganization include the change in total population from 1950 to 1960, the percentage change in the nonwhite population during the same period, and the percentage of dilapidated housing units. Dilapidated housing is defined as the percentage of boarded-up housing units in a city (U.S. Bureau of the Census 1950).

INDICATORS OF DEPRIVATION

As discussed above, both absolute and relative deprivation arguments have been offered as key causes of racial turmoil. Four indicators of absolute deprivation in the nonwhite community are percentage of nonwhites in low-status occupations (household workers, service workers, and common laborers), median years of education for nonwhites, median family income for nonwhites, and nonwhite unemployment rate. Deprivation arguments would hold that nonwhite income and nonwhite education measures depress the rate of race riots while nonwhite participation in low-status occupations and nonwhite unemployment would raise the level of racial unrest.

As Spilerman (1970a) argued, one variant of these theories suggests that poverty produces grievances and unrest to the extent that it affects the minority community disproportionately. In this view, poverty that falls equally on whites and nonwhites might produce class mobilization rather than ethnic and racial tensions. If relative deprivation views are correct, racial unrest would be more likely where the black poverty rate exceeds the white poverty rate. Relative deprivation arguments suggest that racial unrest erupts where there is a substantial racial gap in income, education, and occupation. Four variables are used to test relative deprivation. Each measures the relative position of nonwhites vis-à-vis whites in a community: (1) ratio of the percentage of nonwhite males working in traditionally black occupations to the percentage of white male laborers employed in similar occupations, (2) the ratio of nonwhite median family income to white median family income, (3) the ratio of nonwhite male unemployment rate to the white male unemployment rate, and (4) the ratio of nonwhite median education to white median education. Following relative deprivation arguments, the ratio of black/white income and education should vary inversely with the likelihood of race riots; that is, race riots will decline as the racial gap in attainment is narrowing. In this same view, a higher concentration of nonwhites in low-status occupations and higher participation

in unemployment would generate more racial violence in those communities most affected by these gaps in economic well-being.

MEASURES OF CITY POLITICAL STRUCTURE

In addition to stressing the economic conditions in minority ghettos, Lieberson and Silverman (1965), the U.S. National Advisory Commission (1968), and others emphasized preconditions that structurally blocked access by the black community to routes of political power. The National Advisory Commission (1968) mentioned a combination of at-large elections and "weak mayor" systems as less accountable to minority constituents. Furthermore, the commission concluded that city governments were less sensitive to minority communities when the ratio of city council members to constituents was low. To capture the effects of political sensitivity to minority grievances and concerns, Spilerman (1970a) included four measures of city political structure: population per councilman; percentage of councilmen elected at large; a dummy variable of partisan versus nonpartisan election; and a dummy variable for mayor-council form of city government form of government versus any other form. The general argument tested by Spilerman was that cities that were less responsive to the concerns of minorities would experience more unrest. These characteristics imply that when cities have a lower population per council member and partisan elections, then politicians are likely to be sensitive to racially homogeneous neighborhoods and organizational constituencies (see also Aiken & Alford 1970).

Many arguments about the effects of political structure on race riots rest on the issue of government accountability. For example, Spilerman (1970a) argues that the mayor-council governments would be more responsive to minority concerns, because they could be held accountable by the minority communities directly through elections than would appointed city managers or other forms, such as at-large elections, that could dilute minority influence. Following Spilerman, we expect at-large elections, the ratio of population to council members, and the presence of nonpartisan elections to increase the likelihood of race riots, but the presence of a mayor-council form of city government to decrease the chances of racial unrest.

INDICATORS OF RACIAL COMPETITION

Our competition arguments imply that contraction of the economy produces higher rates of ethnic/racial conflict, as groups vie for a shrinking number of jobs and resources. In addition, resource mobilization and competition arguments suggest that a decline in racial disparities in income ought to produce higher rates of conflict. As formerly disadvantaged minorities come to compete in new job and housing markets, advantaged majority groups attempt to exclude the competitors.

To examine our arguments empirically, we include two measures of competition. The first competition measure is specified as an interaction term between percentage change in population and the overall unemployment rate. This is a measure of *overall competition* in the labor market. The second measure

is *minority competition*. It is specified as an interaction between the nonwhite unemployment rate and percentage change in the nonwhite population in a city from 1950 to 1960. We include both the main effects and interaction terms in our investigation of competition.

In contrast to pure deprivation arguments, theories emphasizing both resource mobilization and competition would hold that as nonwhite income rises relative to white family income, racial protest of all kinds should increase. To the extent that this resource competition argument also holds, we would expect that the rate of race riots would also peak as a result of declining income disparity between the races.[13]

DEPENDENT VARIABLE: EVENT COUNTS

The dependent variable in our analysis uses the distribution of riot counts as grouped events occurring on a particular date to capture the intensity of race/ethnic conflict (Aalen 1978; Petersen 1991). That is, the observed count is aggregated to city counts. In this sample of 204 cities, the mean number of riots was 1.22. Fifty-eight percent (118 cities) had no race riots, which means that 86 cities had at least one race riot over this period. Only two cities, New York and Chicago had a substantially large number of race riots, tallying 23 and 19, respectively. Furthermore, our definition of race riots as large-scale, violent events holds for the observed set of race riots. Virtually all race riots involved fifty or more participants (and 17% had more than 500 participants). In all but three riots, police or bystanders sustained injuries, or there was substantial damage to buildings, or participants were reported as using bricks, stones, firebombs, or other weapons. Targets of race riots were varied, but nearly one-fourth (23%) of all riots observed had the system of justice, city government, or the police as targets of rioting behavior. Another 60% of the observed riots had no clear-cut target or symbol that could be identified from newspaper accounts. The remaining race riots involved a grievance against one particular ethnic group identified as the reason for the rioting (e.g., whites, Jews, or Mexican-Americans).

To capture the environmental causes of variation in outbreaks of racial unrest, we follow Spilerman's lead and estimate effects of covariates on the rate within the framework of Poisson regression.[14] That is, we form regression models for the (daily) count of ethnic events, denoted here by y_t. The regression model represents the rate, λ_t, as a function of observed covariates. To ensure that λ_t can only take nonnegative values, it is parameterized as a loglinear function of the covariates:

$$\lambda_t = \exp(x'_t\beta) \tag{1}$$

This regression model assumes that each observed count of race riots is a realization of a Poisson process whose rate is given by equation 1. In other words, the conditional probability function at time t is given by:

$$Pr(Y_t = y_t | \lambda_t) = \frac{\lambda_t^{y_t} e^{-\lambda_t}}{y_t!} \tag{2}$$

where λ_t is the mean and the variance of the distribution of the dependent variable, i.e.,

$$E(Y_t) = \mathrm{Var}(Y_t) = \lambda_t \tag{3}$$

The Poisson assumption that the expected value of Y_t is equal to its variance is often not justified (Barron 1992; Cameron & Trivedi 1986). In order to test this assumption we also estimated the rate of collective action using negative binomial regression, which allows for the possibility that the variance of the dependent variable is greater than its mean. However, these models did not fit significantly better than the Poisson models, so we report only the Poisson models with heteroskedastic-consistent errors.

Results

We first compare bivariate relationships between covariates and riots counts in our analysis with Spilerman's (1971) results. We then turn to our analysis of the effects of poverty followed by our analysis of labor force competition and racial unrest in the final table.

BIVARIATE CORRELATIONS IN TABLE 1

Virtually all the measures of bivariate association between deprivation and riots shown in Table 1 indicate a lack of support for deprivation arguments. It is striking how similar in magnitude and direction the coefficients are across all three columns. We found that in no case were the signs opposite and, in most cases, the magnitude of the correlations were similar. As Spilerman found, population size, size of the nonwhite population, and southern location are significantly correlated with event counts, while nearly all indicators of social disorganization are negatively correlated with racial unrest. Reflecting the same pattern as in Spilerman's results, we see that while percentage of nonwhite males in low-status occupations is significantly and negatively correlated with race riots, higher median income in both studies were significantly and positively correlated with the count of race riots.

The indicators of political structure show that riot counts are slightly more correlated with political indicators in our riot data than in Spilerman's correlation coefficients in column 1. In particular, we found that the percentage of city-council members elected at large was negatively and significantly correlated with the riot count (where Spilerman reports a nonsignificant but negative correlation with riot counts). However, all the signs of the coefficients remain the same, with the population per councilmen (as a measure of unresponsive government) significantly correlated with race riots, as was the presence of a mayor-council government. Taken together, the pattern of correlations seems remarkably similar across the two studies. Such parallel bivariate relationships lend credibility to the comparisons that follow.

Given the literature on the "urban underclass," it might seem surprising that nonwhite population size and black poverty are not more highly correlated with each other. It is perhaps useful to recall that the poverty measures are taken in 1959, long before the poverty programs were introduced that sharply

reduced poverty in the South and Southwest.[15] Thus, as Wilson (1987) reminds us, poverty in 1959 was more rural and less racially concentrated in urban ghettos than in the 1990s.[16]

NONWHITE POPULATION, POVERTY, AND POLITICAL STRUCTURE

Did racial deprivation raise the rate of race riots over the 1954-93 period? Table 2 shows little evidence that it did.[17] Neither low levels of attainment nor relative gaps in attainment for blacks apparently affect the likelihood of race riots.[18]

Furthermore, the effects of percentage of dilapidated housing and gap in black/white income are the reverse of what deprivation arguments would hypothesize. That is, cities with less dilapidated housing and cities where nonwhites have incomes closer to whites experience higher rates of race riots. The results suggest that improving rather than declining conditions in the black community are associated with race riots. Thus the results in Table 2 are consistent with resource mobilization and competition theory arguments and inconsistent with most deprivation theory arguments.

A notable exception to this statement is the effect of black unemployment. We find in columns 4 and 5 that black unemployment has significant and positive effects. That is, in two out of five models in Table 2, cities with higher rates of unemployment for blacks had significantly higher rates of unrest. This finding suggests that male unemployment plays a role in producing racial tensions. The fact that black unemployment has a significant effect on race riots is also consistent with arguments that black unemployment is a major determinant of the growth of the black underclass (Wilson 1987).

The remainder of our results that show no effects of racial poverty are similar to those reported over twenty years ago by Feagin and Hahn (1973), Lieberson and Silverman (1965), and Spilerman (1971). Extremes in racial poverty or in gaps in attainment do not increase the rate of race riots. Quite the opposite pattern appears to hold.[19]

Other factors also show effects parallel to those found decades ago. City size and the size of the black population have enormous and significant effects on the magnitude of racial unrest in all five columns. These effects are potent and consistent throughout our analysis, even when regional and poverty effects are included in the model.[20] The coefficient of .595 tells us that when the black population is one standard deviation higher than the mean, the rate of race riots increases by 65%. For this reason we include city size and the size of the nonwhite population as controls in all our models.[21]

Two other key indicators of regional and political differences that have powerful effects in Table 2 were unrelated to race riots in Spilerman's analysis. While Spilerman found a negative and significant effect of southern location, we did not. Instead, our results show powerful and positive effects of northeastern location, even when other population and poverty variables are included in the model. In addition, we find that nonpartisan elections produce higher rates of race riots, suggesting support for the original structural responsiveness argument. In this view, partisan electoral politics would be more responsive to minorities who would provide distinct constituencies that would hold local

government accountable for their actions. The effects do support the view that nonpartisan elections raise the rate of racial unrest.

The positive effects found for northeastern location are equally consistent with another ad hoc explanation offered by urban historians. The consistently significant and positive effects found for northeastern location (in all models) are consistent with views that in older northeastern cities (such as New York and Boston) where white immigrants had historically controlled ethnic machine politics, blacks have less political power and stronger motivation to protest (Mink 1986).

Our results are extremely robust: addition of the other indicators did not alter the pattern of effects for dilapidated housing and black income. These results add to the growing doubt that poverty systematically causes unrest. They suggest that cities where blacks are doing relatively better are likely to experience more unrest than when blacks fall further behind whites in family income. Below we offer some explanations of why this might be true.

EFFECTS OF COMPETITION

Arguments from competition theory lead us to consider factors that intensify racial competition over jobs, housing, schools, and other opportunities for advancement. We hypothesized that an increase in the population at the same time that unemployment was high would intensify ethnic/racial conflict. This argument suggests that ethnic/racial competition intensifies in job markets where supply increases at the same time that demand for workers falls. We speculated that both generalized competition for jobs and competition within the minority niche might each affect the rate of race riots in cities.

Does competition add to our understanding of racial unrest? The positive and significant effects of both competition measures in Table 3 suggest that they do. Table 3 adds two indicators of competition. The first two columns measure the effect of rising competition overall in the labor force, while columns 3 and 4 specify the effect of competition within the minority community. We also compare the effects of these competition indicators in models that include those effects found to be important in the previous table. Thus the odd-numbered columns (1 and 3) of Table 3 include the percentage of dilapidated housing and the even-numbered columns (2 and 4) include the ratio of nonwhite to white income. In this way, the relative strength of competition processes can be judged alongside other significant factors.

The positive and significant coefficients for the two interaction effects of competition in all four columns strongly supports the competition argument. In the first two columns, overall competition in the labor force increases the rate of race riots, as expected. Furthermore, addition of this interaction effect does not diminish the significance of other covariates in the models. As in Table 2, the effects of percentage of dilapidated housing and the ratio of nonwhite to white income remain positive and significant where they are included in the model. Furthermore, both specifications of competition seem important. In the first two columns, overall competition raises the rate of race riots. In the second two columns we see that an increase in minority competition also increases the rate.

+ $p < .10$ * $p < .05$ ** $p < .01$ (two-tailed tests)

In both cases, these effects of competition are net of the effects of population size, minority population, and nonwhite income.

How can we interpret the positive effect of competition? Using the same logic and calculations as described above, the three coefficients (for black unemployment, percentage change in nonwhite population, and the interaction between these two) from column 4 suggest that for cities with an average change in black population that experience a black unemployment rate that is one standard deviation higher than the mean rate (13.5% compared to 9.4%), the rate of race riots increases 30-fold. In other words, the interaction term together with main effects of unemployment and changing black population suggest that black unemployment intensifies the consequences of black in-migration and black in-migration intensifies the effects of black unemployment on unrest.

In Table 3 we see that population size and the proportion that is black in cities raises the likelihood of race riots, just as it did in Table 2. Just how big is the effect of minority nonwhite population? Recall that Spilerman found that black population size systematically diminished the effects of poverty and other characteristics. We reasoned that given the relationship found for changes in black population in the earlier period, it might be important to understanding how the proportion of blacks affects racial unrest independent of the in-migration. To isolate the effect of minority population level, we calculated the effect of black population size for cities experiencing an average influx of black migrants during the 1950-60 decade. Comparing cities at the lowest quartile of proportion that is black with the highest quartile, the coefficient of .675 would imply that the rate is increased 275% over this range. The effect of black population size remains an overwhelmingly potent one.

Once we control for population size, dilapidated housing, and competition, we fail to find any effects for most of the absolute and relative deprivation measures in our analysis over forty years.[22] In particular, low levels of black education, high levels of black participation in low-status occupations, as well as racial disparities in education, and disproportionate participation of blacks compared to whites in low-status occupations were unrelated to race riots.

EFFECTS OF POLITICAL STRUCTURE

Prior research suggested that certain changes in the political opportunity structure might be more (or less) conducive to racial tensions and rioting. Political process models echo this suggestion when they point out that several structural features of local government encouraged protest rates as well as other forms of mobilization (McAdam 1982). Spilerman (1971) found little support for these political indicators, despite the widespread assumptions that responsiveness of local government matters.

We investigate this debate as well. Following the political process line of argument, we include measures of nonpartisan elections, mayor-council form of government, proportion of population per council member, and percentage of council members elected at large. Although the zero-order correlations in column 2 of Table 1 suggest that these structural features of city politics were relevant to race riots, our regressions show little evidence in support of this claim. Only one of the hypothesized features of city politics had systematic

effects on race riots over this period (as well as for the entire period): that of nonpartisan elections.

The original argument for inclusion of nonpartisan elections was that cities with nonpartisan politics would be less responsive to minority grievances and demand. Furthermore, Spilerman argued that the unresponsiveness would be more relevant during the 1960s, during the peak of civil-rights activism (Spilerman 1971). Though Spilerman's analysis found that nonwhite population size dwarfed all aspects of city politics, we found that the presence of nonpartisan politics in a city contributes systematically to the occurrence of race riots (holding constant minority population size, city size, and other features of the community).

Our models attempt to distinguish the impact of region from the substantive effects of black population, minority poverty, and competition. This strategy proved important because of the regional concentration of black poverty in the South during this period and the high correlation of competition factors in the Northeast. By including all three regional dummy variables, some of these regional effects can be untangled from the economic competition measures. As in the sixties, the northeastern region produces more racial unrest, and this effect holds even when population composition, poverty, and city political structure are included in the model. Because southern location was significant in Spilerman's original analysis, we were surprised by the fact that southern location had little systematic effects in our analysis.

We would argue that the positive effect found for the northeastern region in all our models is highly consistent with our competition arguments. That is, it was primarily in the Northeast that the U.S. witnessed the beginning of the process of racial competition for the same jobs, housing, and other rewards, as black migrants moved northward (Wilson 1978). Up until recently, employment and wage rates for blacks were substantially better in the North and Northeast than they were in the South. This indicates that during the peak period of racial unrest in the U.S., racial deprivation was disproportionately southern and rural in character (Harris & Wilkins 1988).[23]

Discussion

We began this article with the puzzle that although deprivation theories have been empirically discredited, they remain popular explanations of past and present race riots. We were intrigued by the fact that deprivation explanations cannot account for the fact that race riots occur in places where blacks are relatively better off, or during periods when racial disparities are declining rather than rising. These contradictions shaped our research questions and motivated our reanalysis of the effects of racial poverty.

Farley and Allen (1989) and Wilson (1987) (among many others) have documented changes in minority class structure that provide some clues to understanding this puzzle. In their view, chances for upward mobility have improved for some African Americans but have declined for others at the very bottom of the ladder. The rise in class diversity within the black community is the result of several economic and demographic trends that diminished

opportunities for blacks in the urban working class. At the same time, for educated, middle-class African Americans, opportunities in jobs, suburban housing, and occupational mobility have apparently expanded (Massey & Denton 1993). An often-repeated consequence of these trends is the rapid growth of increasingly poor and black single-parent families that are isolated from city services, education, and employment training (Wilson 1987).

Those who argue that the racial tensions are caused by poverty have linked the growth of the underclass to the persistence of racial tensions and riots in American cities. In this view, the growing underclass constitutes a new and growing threat to harmonious race relations (Massey & Denton 1993). Some have reasoned that these factors could lead ethnic and racial tensions to rise exponentially (Harris & Wilkins 1988). Such an apocalyptic view suggests that American cities are particularly at risk for ethnic violence because of the rising ethnic and racial diversity from rapid rates of immigration and mobility.

Our results have implications for these scenarios. Our analysis does not justify the fears that violence will escalate as the underclass grows. This is because we found little evidence that black poverty or racial disparities in income, education, and occupation caused race riots. Furthermore, we do find that the effects of black poverty are generally opposite from what most deprivation theories would lead us to expect. Cities with more dilapidated housing and lower income for blacks (relative to whites) had significantly lower rates of racial unrest. Finally, we find that competition that is expressed as the contraction of job opportunities created by demographic pressures and unemployment significantly increases the rate of race riots.

These findings are consistent with the view that rates of racial protest rise when racial disadvantages are relatively low. In these cities, the opportunity for blacks to begin to compete alongside whites for similar jobs becomes possible. If the economy expands accordingly, conflict over jobs and housing can be averted. But under conditions of competition, the overall contraction of labor force demand combined with the rising supply of labor from migration intensifies interracial competition and conflict.

Assessing our results from a wide angle, we see that our analysis generally supports the thrust of earlier work from earlier periods, but with a competition twist added to it. Thus we diverge from earlier studies in arguing that it is not the case that deprivation is irrelevant to race riots. Rather, we found there are some indications that cities where blacks are less economically deprived have higher rates of race riots. We saw hints of this finding in earlier work by Spilerman and Lieberson and we found it intriguing. Following the example of the best of the prior research that avoided sample selection bias, we analyzed city characteristics from locations that had no rioting as well as those with multiple riots. Corresponding to Spilerman's and Lieberson's results, we also find that few indicators of poverty, deprivation, or black/white gaps in achievement affect the likelihood of race riots. But we also find one new result: several indicators of rising competition do affect the rate of race riots and they do so significantly.

Despite the popularity of deprivation theories, the empirical analysis shown here suggests that race riots arise where minority deprivation is diminishing and where competition is rising. When migration and immigration create tight

labor markets, black unemployment contributes significantly to unrest in cities. At the same time, our results show that an influx of minorities places additional pressure on the minority community. Our results suggest that one strategy for understanding race riots can be found by exploring the forces that elevate levels of racial competition.

Summary and Conclusions

Our results suggest some avenues of research on the future of race relations. If poverty were directly related to unrest, then the stability of race relations in America's cities would indeed be in peril. Yet our results suggest another more complicated scenario. The pattern of results suggests that poverty alone does not spark racial violence. Instead, competition for increasingly scarce resources such as jobs and housing during periods of increasing population growth produces racial unrest. The relationships uncovered in this research suggest that racial violence is less likely when minority in-migration and immigration are matched by an expanding labor market. For those interested in reducing ethnic/racial conflict, the policy implications are straightforward.

The analysis draws attention to the role of changes in the opportunity structure and how those changes can have both positive and negative effects on race relations. The arguments offered here suggest that both rising and declining economic opportunity can raise rates of racial violence if resources are limited and employment (and other) opportunities remain static. Competition intensifies only to the extent that demands are placed on a closed system of limited resources.

Notes

1. These data on riots are part of a larger data set (1954-1993) on all forms of ethnic/racial collective action that were collected at the SMSA (Standard Metropolitan Statistical Area) level. The analysis first required disaggregation of the SMSA-level data to match city administrative units from Spilerman's list of cities (personal communication). The riot count for 204 cities that were analyzed can be found in Appendix C. Further information on the location of SMSAs and central city units can be obtained from the first author.

2. For examples, see research on white antibusing violence in Useem (1980); ethnic violence in Northern Ireland, in White (1993), and ethnic conflict in the Soviet Union, in Tilly (1991).

3. For national time-series analyses of race riots that extend through the late 1970s, see Kelly and Isaac (1984).

4. The competition arguments developed here also rely on human ecology theories, initially developed by Park (1949). For applications of these theories to instances of ethnic and collective action, see Blalock (1967), Jenkins and Shock (1991), Lieberson (1961), Medrano (1994), Ragin (1977, 1979), See and Wilson (1988), and Wilson (1978). See also the wide range of empirical studies using this perspective in Belanger and Pinard (1991), Olzak and Nagel (1986), Olzak and West (1991), Tilly (1991).

5. Human ecologists emphasize that conflict and competition do not always coincide. Niche separation or ethnic dominance over subordinate groups can also result from competition (Barth 1969).

6. For historical evidence supporting this point, see Senechal (1990), and Tuttle (1970).

7. We began our analysis with race riots from 318 SMSAs during this period and subsequently coded whether a given race riot occurred in a center city of an SMSA or in the suburban or surrounding area. Race riots that were in one of two center cities (for example, in San Francisco rather than in Oakland in the San Francisco-Oakland SMSA) were identified. We then recoded our events to indicate a center city code to coincide with Spilerman's center city code. For comparability between our event data and 1960 census data on cities, we created an event history data set for (1) center cities of SMSAs that existed in (2) 1960 and (3) remained as part of the SMSAs in 1980 or (4) had a population of over 100,000 in 1960. This means that we have virtually all center cities for the SMSAs that existed as SMSAs in 1960. We have several sets of twin center cities that were merged into one SMSA in 1980 (such as Dallas-Fort Worth, San Francisco-Oakland). The analysis treats each of these twin center cities as a separate unit of analysis. The total number of cities for which we have data on covariates and events is 204 center cities (see Appendix C).

8. We exclude here all large-scale unruly events that involved predominately white residents, as in the case of antibusing riots.

9. One reviewer preferred the term *commodity riots* to *race riots* for the present paper, citing Janowitz (1968) and McPhail (1994). In our view, this category is imprecise, because, although violence against property and looting often occurs as part of the actions in a riot, including race riots, it is not the defining feature of race riots. In our view, assuming that all race riots since 1963 are "commodity" riots would lead to confusion of contemporary race riots with other forms of property riots: soccer riots, grain and food riots, looting from brownouts, Luddite violence, and other property-related violence. In making this decision, we emphasize that we are categorizing the event, not the participants. Thus, our coding rule does not require that all participants be from one race. Our coding scheme is available from the first author upon request, as is the list of riot dates.

10. Here we draw a distinction between event analysis and content analysis. Gathering event data for use in event history analysis (used in estimating causal models elaborated here) necessitates reliable information on the dates, duration, and nature of the conflict, rather than information on the specific word counts or analysis of the reporter's characterizations of participants and their actions. Such questions are more appropriate for applying content analysis to specific news reports, papers, or editors.

11. Recent reviews and analyses of newspaper sources of data on events can be found in Franzosi (1987), McCarthy et al. (1996), and Olzak (1992). Empirical analyses of the sources of potential bias problems have been conducted by McCarthy et al. (1996) and Snyder and Kelly (1977).

12. We thank Dan Myers for challenging our use of mainly nonvarying covariates from 1960. He points out that there have been significant changes in the racial composition (or diversity) of these cities across the thirty-five years of this study. Many believe these demographic shifts have exacerbated racial tensions, at least in the recent Los Angeles riots (Baldassare 1994). Ideally, we would have liked to include changing levels of these covariates, but we encountered several obstacles. In particular, the definitions of "black" shifts from nonwhite in 1950 (and 1960) to black in 1970. Even more troubling, the category of non-Hispanic black is distinguished by the census in 1980 and 1990 (and nonwhite ceases to be applied) (Massey & Denton 1988, 1989). Our observations on racial unrest begin in 1960, and so we are constrained to use the antiquated categories of nonwhite for most of our race-specific covariates for this analysis of center cities (but see Olzak, Shanahan & McEneaney 1996).

13. Spilerman's results led us to believe that an absence of effects found for black poverty would be as theoretically interesting and relevant as would any positive or negative effects of poverty. Thus our strategy was to include as many of the indicators as possible. However, because of the multicollinearity between absolute and relative deprivation measures (which are linear combinations of each other), it was not possible to produce analyses of models that include all the indicators described in this section. To avoid estimation problems caused by inflated standard errors, our tables report results for those indicators that survived the log-likelihood test for significant contribution to the overall fit of the model. Concretely, this means that we added each deprivation variable separately in models that included population and

APPENDIX A: Descriptive Statistics for Community Characteristics

Variable	N	Mean	Std. Dev.	Min.	Max.
Ln Population 1960	204	11.82	.97	10.24	15.87
Ln Percent nonwhite 1960	204	-2.17	.92	-4.51	-.60

Overall competition 1960 (ln population * total unemployment)	204	.01	.03	-.01	.23
Minority competition 1960 (ln percent nonwhite * nonwhite unemployment)	204	.07	.08	-.13	.45

political measures. Below we discuss the results for all these covariates in the text so that readers can compare the results with Spilerman's analyses.

14. For another sociological application of Poisson regression applied to another form of racial violence, see Beck and Tolnay (1994).

15. Appendixes A and B present the means, standard deviations, and correlations of the key covariates in Tables 2 and 3. While multicollinearity is often present in analyses of poverty and racial composition measures, it is interesting that the correlations among the natural log of percentage nonwhite with the other measures of "underclass poverty" (nonwhite unemployment rate, percentage of dilapidated housing, and relative income and education) are so low for these 204 cities. The deprivation and relative deprivation indicators are of course highly collinear with each other. In most cases, this required that we enter them singly in each model.

16. We agree that it would have been preferable to distinguish race/ethnic categories more precisely. Current research using data from the 1980s and 1990s now distinguishes Hispanics from non-Hispanics, by race. For examples, see Massey and Denton (1989, 1993). Unfortunately, these key distinctions are unavailable for earlier decades. Concretely, this means that Spilerman's original data is limited by the prevailing racial category of nonwhite, which we now know contains some (unknown) percentage of Hispanics, Asians, and Native Americans, who classified themselves as nonwhite.

17. We examined all the covariates of deprivation and relative deprivation (from Table 1) and found that only the effects of dilapidated housing and the ratio of nonwhite to white family income were significant. For this reason we focus on only those measures that had systematic effects.

18. The presence of multicollinearity required that we enter the covariates independently in most cases. This was particularly true for the socioeconomic indicators of nonwhite education and income (the Pearson coefficient is .70). Although we investigated the effects of all the covariates listed in Table 1, only those reported below had any systematic effects once population size and minority composition were taken into effect. In models analyzed (but not shown), we found no significant effects for the poverty indicators: median black education, black participation in low-status occupations, and black unemployment level (by itself) apparently has little systematic impact on racial unrest.

19. Table 2 reports a likelihood ratio to compare the goodness of fit for nested models. If the null hypothesis holds, then the difference between the likelihood ratios has a chi-square distribution with degrees of freedom equal to the number of constraints that have been freed. For example, to examine whether the addition of dilapidated housing improves the fit, compare the log-likelihood of -37.54 in column 2 to -42.04 in column 2. Twice the difference is 9.0, which is significant at the .01 level (with one degree of freedom).

20. Since this effect also plays a central role in Spilerman's (1970a) conclusions, it may be useful to explain how this effect is calculated over the observed range of black population size. For example, the coefficient for the log of population size in 1960 is .712 in column 1. This parameter suggests that when city size is one standard deviation higher than the mean, race riots nearly double. This effect is calculated by taking the exponent of the product of the effect of black population size, .712, at one standard deviation above the mean and comparing this effect to that found at the mean for this variable.

21. For further explanation of interpretation of Poisson regression coefficients, see Liao (1994:72-74).

22. We remind readers that we do not have direct measures of perceived levels of deprivation or aspirations, but rather, like Spilerman, we use only indirect indicators: black/white median income, education, and low-status occupations.

23. One of the anonymous reviewers asked if we did analyses to discover if competition levels differed in Chicago and New York (the two cities with the highest rate of race riots in our data). If we understand this comment, there is an alternative hypothesis underlying this comment worth investigating. Following this logic, we ran the same regressions as we report in Tables 2 and 3, omitting these two "high riot-count" cities. Our competition results remained the same, which was reassuring. In general, however, our modeling strategy is to try to capture the effects of "outlier" cities by including the appropriate covariates rather than by including specific city dummy variables (e.g., including a dummy variable for both Chicago and New

Labor Force Transitions among Older African American and White Men*

Abstract

Using a life-course/opportunity-cost framework, we study racial differences in labor force behavior among African American and white men aged 55 to 69. A multifaceted measure of labor force behavior is examined within a longitudinal framework. We perform the analyses with a merged sample of the 1984 and 1985 Survey of Income and Program Participation, and we find that the most stable status is not working, followed by full-time, part-time, and unemployed statuses. Results from multivariate logistic regression change models show race-specific effects of age, health, and not-working status on several labor force status and attrition contrasts. Researchers have much to gain by continuing to consider racial differences in late-life labor force behavior and by focusing on contemporaneous and lagged measures of life-course variables.

Given the increasing diversity of the American labor force, the sociological value of traditional definitions of retirement is decreasing because labor force withdrawal has become much more complex than moving directly from full-time attachment to work to full cessation of work (see Atchley 1982). For a substantial number of older persons, labor force exit is a process and not a single, irreversible event. In addition, the process varies with sociodemographic characteristics such as race, ethnicity, and gender. In fact, some observers argue that retirement is more a white phenomenon than an African American one (Hayward, Friedman & Chen 1996).

For these reasons and others, such as cohort progression and change in state welfare and pension policies (see Henretta 1992), the popular image of a white,

 Social Forces, March 1996, 74(3):963-982

middle-class male voluntarily moving into retirement at age 65 (or earlier) after years of service to a company is fast becoming an anachronism for a substantial portion of American workers. Thus, the question is whether a classic model of retirement behavior (e.g., Kotlikoff & Wise 1989; Quinn, Burkhauser & Myers 1990) is too narrowly defined for the heterogenous U.S. labor pool.

We argue that alternative approaches to the classic model of retirement are needed to help better understand race differences in labor force transitions. There are many reasons to expect differences between African Americans and whites. Compared to whites, African Americans on average have worse health, less education, fewer economic resources, and suffer the negative effects of discrimination, generally having access to the least desirable jobs. The impact of these reduced life chances accumulate over the life course so that by the time African Americans approach the traditional retirement age their opportunities for an "orderly" exit are reduced. As a result, African Americans have a weaker attachment to the labor force later in life and lower opportunity costs than whites. These issues lead us to believe that African American and white men will make different decisions about work in later life.

This article examines these issues by comparing late-life labor force transitions between African American and white men in the U.S. during the mid-1980s, using pooled data from the 1984 and 1985 panels of the Survey of Income and Program Participation. In order to accomplish this, we establish a measure of late-life labor force behavior that allows us to evaluate reductions in number of work hours, complete withdrawal from the labor market, reentry into the labor force, and other transitions.

Race and Transitions in Late-Life Labor Force Status

A more refined model of "retirement" must first take into account the myriad forms and causes of retirement. One of these, early retirement, is far more common today than in previous decades. For some older persons, earlier retirement combined with increasing longevity provides a variety of opportunities for reentry into the labor force (Anderson, Burkhauser & Butler 1984; Beck 1985; Hayward, Hardy & Liu 1994). Reentry may mean part-time or full-time employment, often in occupations similar to the individual's primary occupation before retirement (Hayward, Hardy & Liu 1994).

Many older persons do not voluntarily retire but rather fade from labor force activity as a result of being laid off or fired. Some portion of involuntary exits from the labor force in later life are brought on by protracted spells of illness or disability (e.g., Chirikos & Nestel 1989; Hayward & Grady 1990). Under such circumstances, the maintenance of a full-time occupation becomes more difficult, if not impossible. Yet these circumstances may be reversible. Full or partial recovery from an illness or disability may allow an older person to reenter the job market, at least at a reduced level of participation, and likely in a different occupation. Still, whatever the cause of involuntary retirement, older unemployed workers face two barriers to new employment: ageism and the possession of obsolete skills (e.g., DeViney & O'Rand 1988; Lazcko 1989).

A retirement model must also account for labor force behavior among diverse sociodemographic groups. A model based on the behavior of white males may not be entirely satisfactory for explaining similar activities among women, members of other racial and ethnic groups, and the chronically poor or ill (e.g., Gibson 1987, 1991a; Jackson & Gibson 1985; Pienta, Burr & Mutchler 1994; Szinovacz 1985). Weak attachments to the labor market early in life, poor or unstable health, poor earnings opportunities, and the absence of pension income are potential sources of work instability in later life, especially among African Americans (Parnes & Nestel 1981). Those who experience less than optimal opportunity and reward structures over the life course possess labor market histories, economic profiles, and health/disability statuses that preclude a classic transition into permanent retirement.

Although research continues to document patterns of racial diversity in labor force participation in the U.S. (see Smith 1986; U.S. Bureau of Labor Statistics 1994; Welch 1990), much of our knowledge of late-life labor force patterns is still based on white males who retired in the 1970s and early 1980s. As recently as 1985, Jackson and Gibson (1985) state that "in spite of the need, virtually no research has focused on the work and retirement of older blacks" (194). A small number of social scientists have heeded this call. Recent studies comparing racial groups near retirement age agree that some important differences by race are apparent (Gibson 1987, 1991a; Gohmann 1990; Gustman & Steinmeier 1986; Hayward, Friedman & Chen 1996). These differences suggest to us that further study of the work patterns and transition behavior of older African Americans can help in the design of social policy as well as in the development of theory about labor force behavior within heterogeneous populations.

For example, Jackson and Gibson (1985) argue that the term *retirement* may have little meaning for many African Americans, who do not experience a marked decrease in work time in later life, but rather display continuous instability in work behavior over the life course until death or full disability. Gibson (1987) argues further that many older African Americans occupy an increasingly common labor force category that she terms the *unretired retired*. In her view, this phenomenon fits hand-in-hand with upward trends in physical disability and declines in labor force participation.

Scholars from different disciplines have discussed some of the reasons for the apparent correlation between increasing physical disability and decreasing labor force participation among older African Americans. Gibson (1987, 1991a) suggests that African Americans' relatively frequent adoption of the sick role stems from the increasing availability of disability benefits and the relatively low economic value of available labor market compensation and benefit levels. This in turn lowers their likelihood of claiming subjective retirement and increases their likelihood of subjective disability. Social and psychological benefits have also been attributed to this phenomenon.

Similar explanations have been suggested by others (Chirikos & Nestel 1985; Hayward, Friedman & Chen 1996; Parsons 1980). For example, Parsons (1980) finds a significant race effect when evaluating the impact of replacement income from Social Security disability benefits on labor force participation.[1] African Americans are more likely than their white counterparts to elect not to

participate in the labor force in the presence of disability benefits. However, the race effect disappears when Parsons controls for state-level differences in welfare benefits.

Hayward, Friedman, and Chen (1996), employing panel data from the National Longitudinal Survey of Older Men, find that the poorer health of African Americans compared with that of whites contributes to earlier exits from the labor force. In general, the empirical evidence about the existence and nature of race differences in the relationship between health and labor force participation patterns is mixed: Some researchers argue that race differences are based on subjective evaluations and others argue that the race differences are based on objective differences in health status. We expect that both the subjective evaluation of poor health/disability status and the actual race differences in health observed by others play important roles in the decision to work.[2]

Our interest in describing racial differences in labor force transitions is not limited to health/disability issues. In this study, we also incorporate economic characteristics of the individual. Since the economic histories of older African Americans are known to be poorer than those of older whites, we expect income in later life to play an important part in deciding how much labor, if any, to engage in. For example, older persons with fewer economic resources are often motivated to work part-time after withdrawing from a full-time position. In addition, persons who are not working at one point in time may need to reenter the labor market to make up for short-falls in pension income, if it exists at all.

Socioeconomic class may also account for differences in labor force instability between racial groups. Persons who are satisfied with their occupations are motivated to maintain longer attachments to the labor force, suggesting greater stability. Family status also impacts work decisions, and race differences in family stability and structure are well documented. Generally, the literature shows that married persons frequently retire jointly and may leave the work force earlier (Henretta & O'Rand 1983). However, little work has been reported to guide our expectations about racial differences in marital status effects on late-life labor force participation.

Age is also central to the decision process. Even within relatively narrow age ranges, age may play a role in racial differences in labor force behavior. For the youngest of the older persons considered in most retirement research, there may be institutional barriers to early withdrawal (e.g., eligibility for Social Security). On the other hand, institutional rules for private pension receipt may encourage early withdrawal for persons approaching traditional retirement ages. Since African Americans are less likely than whites to have access to private pensions and more likely to rely on government retirement programs, they may leave the labor force later in life or substitute part-time work for full-time work until they can take advantage of Social Security benefits.

Net of the effects of health status, discrimination, work history, and socioeconomic status, we suggest that another reason for expecting race differences centers on the nonmonetary qualities of jobs. In other words, the poor intrinsic value of many jobs available to African Americans may motivate them to seek alternatives to full or continuous participation. Low levels of

intrinsic value in available jobs may influence some African American men to report disability as a status rather than retirement, to reduce their commitment to the labor force by reducing their hours, or to leave the labor force and not reenter. This may be even more likely when Social Security or disability payments provide a relatively fair substitute for the economic rewards available in the job market — compensation which is on average low for African Americans.

Sociological literature contains support for this idea. For example, Jencks, Perman and Rainwater (1988) divide the desirability of jobs into two categories: monetary and nonmonetary. They find that when African Americans and whites rate their jobs, only one-fifth of the difference in their ratings is attributable to monetary concerns. The remaining difference in job ratings has to do with the nonmonetary characteristics (e.g., level of supervision, risk of job loss, repetition in job tasks). Jencks, Perman and Rainwater (1988) show that, in general, jobs held by African Americans are less desirable than those held by whites.

To summarize, we have argued that African Americans and whites differ in terms of the central economic, demographic, and social factors that influence labor force behavior in later life. In addition, we believe that African Americans and whites with the same levels of these important attributes respond differently when faced with decisions about the level of labor force attachment they maintain in the later stages of the working life cycle. The model we present here assumes that individuals consider both economic and noneconomic factors, as well as perceived labor market alternatives, when evaluating their current employment or nonemployment. Our model is consistent with life-course perspectives on work and retirement put forth in the sociological and economic literatures, but we do not presume to capture all the relevant motivating factors.[3] Instead, we hope to establish a foundation for more extensive studies of the late-life labor force behavior of nonwhites and women. We start by providing descriptive information about variation in labor force transitions by race and by developing insights into the employment-related behavioral differences among African American and white males. Below we discuss the methods that allow us to capture a view of this complex and dynamic behavior.

Data and Methods

We use data from a pooled sample of respondents from the 1984 and 1985 panels of the Survey of Income and Program Participation (SIPP). Pooling the data allows us to obtain a larger sample. The SIPP is designed to provide longitudinal data for a nationally representative sample of the civilian, noninstitutionalized population (see Kasprzyk et al. 1987 for a detailed discussion of the SIPP). Panels are fielded for two and a half years; the 1984 panel began in October 1983, and the 1985 panel began in February 1985. Because of the staggered interviewing, our data covers the period from January 1984 to December 1986 (24 months of observation).

This study includes non-Hispanic African American and non-Hispanic white men aged 55 to 69 who were ether included in both the first and seventh wave of each survey, or who died or became institutionalized during this period.

Those who left the sample for other reasons (e.g., those who refused to continue participating, and those who moved out of the interview area) are excluded from the sample, resulting in a 15.7% reduction. We account for features of the sample design and patterns of attrition by applying modified sample weights. We begin with the cross-sectional weight provided by the Census Bureau and included in the SIPP data for the initial wave of observation. We then adjust these weights to accommodate attrition over the period of study, taking into account differential attrition by race and panel (1984/1985). Our strategies for weighting the sample data were guided by discussions in Kasprzyk et al. 1989. Details of this weight adjustment process are available from the authors.

Indicators traditionally used to examine complex labor force behavior are somewhat constrained, often based on cross-sectional or retrospective summary indicators of labor force participation or nonparticipation (e.g., Parsons 1980). In addition, measures of subjective retirement can be clouded by other mitigating options, such as subjective disability (Gibson 1987). Finally, some researchers have employed receipt of pension income as a dimension of labor force status. This strategy may leave out many disadvantaged persons because of their lifelong poor market positions (Jackson & Gibson 1985).

We overcome these limitations by developing a cross-sectional measure of different levels of labor force participation (e.g., part-time vs. full-time work). We can then generate this measure for different time points, which allows us to infer changes in status (e.g., reentry, full withdrawal).

Our labor force measure is based primarily on a summary of work experiences in the month before each interview. We include four labor force statuses: (1) full-time work, which includes individuals who usually worked 35 or more hours per week; (2) part-time work, which includes individuals who usually worked fewer than 35 hours per week; (3) unemployed, which includes individuals who experienced spells of unemployment during the month; and (4) not in the labor force, which includes individuals who had no work attachment in the month prior to interview.[4] For our transition analysis, we added another category, which includes those individuals who either died or were institutionalized during the observation period. See Chirikos & Nestel 1989 for a discussion of the importance of the mortality outcome in studies of late-life labor force behavior: data on reason for attrition were provided to the authors by the U.S. Bureau of the Census.

The independent variables in the multivariate analyses are taken from wave 1 of each panel. Disability status is a central variable in the study of late-life labor force behavior (for a recent discussion of current research in this area, see Mutchler et al. 1994). We measure disability status by response to the question "Does _____ have a physical, mental or other health condition that limits the kind or amount of work _____ can do?" This question is asked of the respondent in wave 1 (for those younger than 70) and is a standard question for the presence of a work-limiting health condition (1 = presence of a work-limiting health condition).[5]

We include a dummy variable for marital status because late-life labor force behavior is known to vary by this characteristic (1 = married). We also control for age of respondent inasmuch as our study sample crosses younger age respondents who are less likely to be out of the labor force and respondents

from older age groups who are more likely to be out of the labor force due both to normative pressures and institutional factors (e.g., eligibility for public and private pensions and Medicare). To capture the anticipated nonlinearity in the age effect associated with program eligibility requirements, we also include in our models an age spline function. Persons aged 55 to 61 are assigned a zero and persons aged 62 and older are assigned a value equivalent to their age minus 61 (thus, 62 = 1, 63 = 2, 64 = 3, and so on). The age spline function is used in conjunction with the age variable in the multivariate models.

Current income is measured as the respondent's reported total personal income in the four months prior to first interview (own income only; we use the natural log of income in the multivariate analyses). Number of years of completed education for each respondent is included as an indicator of social class. Finally, we include a dummy variable to indicate if the respondent was part of the 1984 or 1985 SIPP panel (1 = 1984 panel). This variable is designed to pick up any gross differences in sample design and period effects across the two panels. Descriptive information based on time 2 (wave 7) labor force status and the variables outlined above are presented in the Appendix. We leave it to the reader to inspect these data.

We present the results of our analysis in two phases. First, we present transition rate matrices for both races combined and for each race group, capturing the stability and change in work status (and attrition) between wave 1 and wave 7. Second, we estimate multivariate logistic regression models of labor force transitions. Separate analyses are conducted for each race group. Because the dependent variable is categorical and unordered, we use multinomial logistic regression (e.g., Hanushek & Jackson 1977; Maddala 1983). More details on the multivariate analysis are given below.

Results

Table 1 describes the labor force transition rates for the 24-month period for both races combined. The table shows that a great deal of variability occurs in terms of how much movement surrounds a given labor force category. For example, of the men reporting they were not in the labor force at first observation, nearly 86% were not in the labor force at the final observation. This suggests substantial stability among nonworkers in this age group.[6] Of those who did leave the not-working status, 8.0% died or became institutionalized, and 5.5% reentered the labor force either as full-time or part-time workers.

Full-time workers were a less stable group: Just under 69% reported this status at final observation. In contrast, fewer than half (47%) of those reporting part-time work at first observation reported the same status at final observation. Nearly 20% had moved to full-time work 24 months later, and 30% left the labor force altogether. Not surprisingly, the unemployed were a very unstable group: Fewer than 14% continued to report this status at final observation. The largest share of those unemployed at first observation left the labor force during the two-year period (46.5%).

Among the four labor force statuses identified in wave 1, Table 1 shows unique patterns of mortality and health by labor force status at time 2 (wave 7).

TABLE 1: Labor Force Transitions for Full Sample, Wave 1 to Wave 7[a]

	Labor Force Status (Wave 7)					
Labor force status (wave 1)	Full-Time (%)	Part-Time (%)	Unemployed (%)	Not Working (%)	Died/ Inst. (%)	Total (Wave 1) (%)
Full-time	68.9	8.1	2.4	18.5	2.0	100.0 (1,684)
Part-time	19.4	47.2	.2	29.7	3.4	100.0 (302)
Unemployed	22.4	12.3	13.9	46.5	5.0	100.0 (107)
Not working	2.0	3.5	.7	85.8	8.0	100.0 (1,640)
Total (wave 7)	(1,281)	(348)	(63)	(1,860)	(181)	

[a] Total unweighted counts for each labor force status in wave 1 and wave 7 are given in parentheses (weighted sample size = 5,249, unweighted sample size = 3,733). Data are weighted as discussed in text. Differences between sum of categories and reported totals due to rounding error.

Full-time workers are the least likely to die or become institutionalized, and those who are not working are the most likely to have died or become institutionalized. These relationships are most certainly confounded with age differences across the four labor force statuses identified here. Some of the age effect will be captured in our multivariate models (discussed below).

Next, we turn to a discussion of similar transition rate matrices broken down by race — the primary focus of our study (see Table 2). The reader should be aware that some cells in the matrices contain sampling zeros. Table 2 shows the transition rates for the white male and African American male samples.

While there are some notable similarities between older African American men and older white men in labor force transitions, there are some interesting differences as well.[7] One similarity is the relative stability of the not-working status for each group across the two time points (86.3% for whites and 81% for African Americans). Another is the instability of part-time work status. Part-time work status was the most unstable of the two working statuses reported here (full-time and part-time), which supports the findings of other researchers (see Hayward, Hardy & Liu 1994). Part-time work is a function of many factors at this age, including (1) a preference for partial retirement over full retirement (see Honig & Hanoch 1985), (2) the need to cover income

TABLE 2: Labor Force Transitions by Race, Wave 1 to Wave 7

	White Sample					
	Labor Force Status (Wave 7)					
Labor force status (wave 1)	Full-Time (%)	Part-Time (%)	Un-employed (%)	Not Working (%)	Died/ Inst. (%)	Total (Wave 1) (%)
Full-time	68.6	8.1	2.6	18.6	2.2	100.0 (1,563)
Part-time	18.8	47.8	0.0	29.7	3.7	100.0 (281)
Unemployed	22.2	11.0	15.9	46.4	4.5	100.0 (94)
Not working	2.1	3.6	.7	86.3	7.4	100.0 (1,485)
Total (wave 7)	(1,178)	(326)	(60)	(1,702)	(157)	

	African American Sample					
	Labor Force Status (Wave 7)					
Labor force status (wave 1)	Full-Time (%)	Part-Time (%)	Un-employed (%)	Not Working (%)	Died/ Inst. (%)	Total (Wave 1) (%)
Full-time	73.9	8.0	0.0	17.4	.7	100.0 (121)
Part-time	28.1	38.7	3.4	29.8	0.0	100.0 (21)
Unemployed	24.3	20.5	0.0	46.8	8.4	100.0 (13)
Not working	1.3	2.2	1.1	81.0	14.3	100.0 (155)
Total (wave 7)	(103)	(22)	(3)	(158)	(24)	

[a] Total unweighted counts for each labor force status in wave 1 and wave 7 are given in parentheses. Data are weighted as discussed in the text (weighted African American sample size = 435, unweighted African American sample size = 310 and weighted white sample size = 4,796 and unweighted white sample size = 3,423). Differences between sum of categories and reported totals are due to rounding error.

shortfalls in the context of what would otherwise be a time of full retirement, and (3) an inability to find full-time employment in a slack job market for the reasons noted earlier in the article.

We also found two major differences between the two races. First, among those who started the survey in the labor force (either full-time or part-time), the fraction who died or became institutionalized (mostly in nursing homes at this age) is much lower for African American men than for white men. Yet among those who began the observation period not working, twice as many African American men died or were institutionalized compared to white men (14.3% vs. 7.4%). This implies that health may be a more important predictor of labor force status and transitions for African American men than it is for white men.

A second major difference by race centers on part-time work status. African American men who begin the observation period as part-time workers are much more likely to move into full-time employment than are their white counterparts (28.1% vs. 18.8%). This difference in the rate of transition into full-time work is likely indicative of the life-long instability in labor force attachment (and opportunity) among African American males.

To establish the statistical significance of the differences identified in Table 2, we fit a series of hierarchical loglinear models to the origin by destination by race cross-classification. The fit of the various models is shown in Table 3. When we compare the results from models 2 and 1, we can see that the majority of the association in the table is between the origin and destination status, but the model does not adequately fit the data. Including interactions for race-by-origin (model 3) or race-by-destination (model 4) or both interaction terms simultaneously (model 5) improves the fit of the data, but the overall fit of the model is still inadequate. Thus, the saturated model, including the three-way interaction between origin, destination, and race, is required to fit the observed association. This suggests that the patterns shown in Table 2 are significantly different for this sample of white and African American men.

Multivariate Analyses

As indicated by the results presented in Table 3, the overall patterns of labor force status and transitions observed in Table 2 represent statistically significant race differences. At this point we turn to the possible effects of background characteristics on these transitions.

For this phase, we estimate separate multinomial logistic regression models for the African American and white samples, using weighted data, as discussed earlier. This form of the multinomial logit model provides a comparison of categorical outcomes through a series of binomial contrasts. We employ the CATMOD procedure from the SAS statistical software to estimate these models. More formally, the model for this analysis is given below:

$$Log(P_j/P_m) = Xb_j$$

This model specifies the log-likelihood of being in labor force category j relative to labor force category *m* (or sample exit through death or institutionalization)

TABLE 3: Fit Statistics for Alternate Loglinear Models Assessing the Association between Wave 1 Labor Force Status (A), Wave 7 Labor Force Status (B), and Race (C)[a]

Marginals fit to the data	Likelihood Ratio Chi-Square	df	p	D
1. A B C	3,738.991	31	.000	.368
2. A * B C	56.821	19	.005	.016
3. A * B A * C	42.287	16	.000	.012
4. A * B B * C	43.339	15	.000	.011
5. A * B A * C B * C	30.951	12	.002	.007

[a] Data are weighted as discussed in text.

as a function of X, the set of explanatory variables given earlier, and b_j, the vector of parameters associated with category j.

Our multivariate logistic regression analyses focus on labor force status at time 2 (wave 7 of the SIPP observation period) as the outcome variable. The predictors in this model include the variables described above in the Data and Methods section. We also include in these models respondent's labor force status at origin (wave 1), and exclude from the model a reference group for one of the labor force statuses at time 1 that is the same as the reference category at time 2 (e.g., full-time origin is not included when the reference category at time 2 is full-time work). This allows us to evaluate more intuitively the impact of change in labor force status across the two time points. For example, when we compare working full-time with working part-time at time 2, we generate coefficients for start statuses of not working and part-time working at time 1. Here we are able to estimate the log-likelihood of moving from not-working status at time 1 to either full-time or part-time status at time 2 (reentry into the labor market).

In general, the coefficients represent the estimated log-likelihood of moving to one of two labor force statuses or to a single labor force status or sample exit by dying or being institutionalized at wave 7. In the first part of the analysis reported in Table 4, the reference category in contrasts 1 through 3 (full-time vs. part-time, full-time vs. not working, full-time vs. death/institutionalization) is working full-time at time 1. Normally, these are the only results that would be reported. However, to give the reader a full picture of all possible transition contrasts, we present in contrasts 4 through 6 the nonredundant labor force comparisons not captured in the first three contrasts (not working vs. part-time, not working vs. death or institutionalization, and part-time vs. death or institutionalization).[8]

TABLE 4: Results from Logistic Regression Models of Transitions in Labor Force Status among Older African American and White Men[a]

	Labor Force Status (Wave 7)

* p < .05 ** p < .01 + .05 < p < .10 (two-tailed test)

For each labor force status contrast, the results from the African American model are presented in the first column and the results from the white model are presented in the second column to facilitate comparisons. Differences in racial contrasts for each pair of coefficients significant at the .05 probability level or better are enclosed in boxes. Comparative results not enclosed in boxes suggest that observed race-specific patterns are not significantly different across the African American and white samples.

The results in Table 4 show strong positive effects of initial labor force status on the likelihood of changing labor force status for each race group. In general, this suggests that net of the other variables in the model, there is considerable labor force stability among most categories of work. This supports the interpretation of some of the results from Tables 1 and 2. With two exceptions, these results also show that the association between starting and ending work status is essentially the same for African Americans and whites, *net of health, socioeconomic status, and demographic characteristics.*

The two exceptions to this pattern occur among those who start the observation period in the not-working status. Both African American and white men in this group are more likely to die or become institutionalized than those who start the period working either part-time or full-time. However, among men who start the period not working, African Americans are more likely than whites in these two contrasts to die or become institutionalized. This suggests that African American men who are not working at the start of the observation period have higher chances of dying over the two-year period than white men.

The effects of age for the two groups differ only in the part-time versus full-time contrast — the decision of how many hours to work. The greater likelihood for older workers to report other than *full-time work* as an ending status is more pronounced for African American men than for white men. The age spline effect (capturing the flattening of the age effect beginning at age 62) is also more substantial for African American men than for their white counterparts when we contrast death/institutionalization and full-time work.

Together these effects demonstrate that African American men are less likely to work full-time at an earlier point in the working life cycle than white men. The effects of health and socioeconomic status also differ between the groups. African American men with work-limiting health conditions are significantly more likely than similar whites to choose part-time instead of full-time work, or to leave the labor force altogether. Higher income men of both races are significantly more likely than their low-income counterparts to be nonworkers rather than part-time workers, yet the difference is significantly larger among African American men than among white men. Thus African American males with sufficient income are more likely to take advantage of this resource to leave the labor force at the later stages of the working life cycle, net of the other variables in the model.

Taken as a whole, these results suggest that although the transition patterns show more similarities than differences among African American and white men, there are some meaningful differences in the *process* associated with those transitions. This appears to be particularly relevant to the decision to work full-time or part-time rather than leave the labor force altogether. In particular, older African American men apparently respond more strongly to health and socioeconomic status than whites and leave full-time work at an earlier age.

Although we are not able to test the "good jobs" hypothesis directly with the SIPP data, racial differences in attachment to the labor force are likely at least in part

to be the result of older African American men rejecting work because of the desirability of the jobs available to them. In other words, our results show that African American and white men respond differently to decisions about work given similar levels of income, age and health. This differential response may be partly related to the kinds of work done, physical stress of the job, and the job's intrinsic reward structure. The results of this analysis for this hypothesis are only suggestive and should be followed up with research that more explicitly tests these ideas.

Discussion

As we have discussed, permanent withdrawal from the labor force in later life is for many persons a process and not a single event. This process often includes spells of unemployment before an involuntary and complete exit from working life. The process may also include either partial retirement or part-time work. Further, many older persons leave their major lifetime occupations only to return to the labor force within a short period of time.

With these issues in mind, this study is designed to assess differences among older white and African American men in their work and nonwork characteristics and in their transition behavior over a 24-month observation period. Existing research documents important differences in labor force participation *levels* between African American and white men measured at single points in time throughout the adult life cycle. In this study, we document meaningful differences in labor force *transition rates* using panel data at later stages of the working life cycle. Multivariate analyses of labor force transitions indicate that statistical associations among key labor force statuses and a set of theoretically important predictors, such as health and socioeconomic status, differ significantly by race. Accordingly, we conclude that racial differences in later life labor force outcomes are important and should continue to be explored.

For example, as we noted earlier, some observers claim that African Americans are more likely to assume the disabled sick role in old age than whites, which may partially account for their greater proportion of the "unretired retired" (Gibson 1987; Jackson & Gibson 1985). One of the assumptions is that subjectively assessing oneself as disabled may be a way of coping with the inability to find a desirable job or to retire in a more traditional fashion.

However, evidence provided here and elsewhere (Hayward, Friedman & Chen 1996) suggests that the African American "unretired retired" are not simply claiming poor health as a social psychological adjustment mechanism. As we found, African American men who began the observation period not working were twice as likely as white men to die or become institutionalized, indicating that they have objectively poorer health. This may show that the relationship between race, health, and labor force participation is more complex, requiring further evaluation. That is, death and institutionalization are "objective" states whereas claims of disability reflect a more nebulous mix of subjective and objective realities. (Note that African Americans are on average much less likely to make use of institutions in old age than whites; see Burr 1990.) Given differences in the transition to the death/institutionalized state in the SIPP data, African Americans who are not working in old age would appear to be in objectively worse health than their white counterparts and this poor health negatively impacts their labor force participation. For at least some substantial portion of older African American men, they are not simply claiming poor health as

a social psychological adjustment mechanism. Rather they are in worse health and this effects their level of labor force participation.

Another potentially fruitful avenue for future research is suggested by the hypothesis that older African American men, who have suffered economic disadvantage throughout their working lives, may be prone to a less stable attachment to the labor force if there are few or no desirable jobs available. In such cases, they likely prefer to reduce their work hours or remain out of the labor force if other sources of income (e.g., disability income, Social Security) come close to meeting their economic needs. While our work does not directly assess this possibility due to data limitations, the results suggest these explanations may have some utility.

What does the future hold for the labor force behavior of older African American and white men? During the last 10 years, American corporations have engaged in downsizing through massive layoffs, often laying off persons in high skilled, middle and upper white-collar positions as well as persons in less skilled positions. A disproportionate number of these jobs are held by white men. For many older white men, these layoffs have disrupted otherwise orderly careers and created difficult economic circumstances along with uncertain retirement expectations and horizons. If this restructuring continues, the labor force behavior of older white men may begin to resemble the less stable behavior characteristic of large segments of the older African American male population. This is another topic for future research.

Finally, our study also contributes to the continuity of research into labor force behavior among older persons in the U.S. The behavior of earlier cohorts of men has been thoroughly chronicled in national surveys such as the Retirement History Survey, the National Longitudinal Surveys of Older Men and Women, and the Panel Study of Income Dynamics. And the long anticipated Health and Retirement Survey will allow researchers to examine the behavior of a later set of birth cohorts not captured elsewhere. The present study and others like it that rely on the SIPP allow researchers to fill the gap between the studies just mentioned. Such descriptive research allows for continuity in the coverage of birth cohorts and provides the opportunity for establishing policy and theory based on a continuum of information.

Notes

1. Parsons (1980) uses a somewhat dubious control for health in his cross-sectional models: subsequent mortality experience after the observation point. One of the contributions of the present research is a longitudinal evaluation of multifaceted labor force behavior with health measured at time 1 and mortality, if present, measured at time 2.

2. Research on the association between health status and labor force behavior at the end of the working life cycle for the general population is well developed. Many studies have demonstrated a negative association between health and labor force activity (e.g., Ekerdt, Bosse & LoCastro 1983; Hardy 1982; Hardy & Pavalko 1986; Hausman & Wise 1985; Hayward & Grady 1990; Hayward, Friedman & Chen 1996). While health limitations typically affect work status, they do not necessarily signal permanent labor force withdrawal. Instead, they may result in reduced participation, a job change, or temporary withdrawal (Hausman & Wise 1985; Hayward & Grady 1990). In addition, persons may recover from poor health or temporary disabilities and reenter the labor force (see Hayward, Friedman & Chen 1996). We expect that the linkage between race, health, and the dynamics of labor force behavior are based at least partially on the actual health differences by race.

3. One variable not included in the present analysis of race differences in labor force transitions is pension eligibility. Because of the location of the relevant questions in the SIPP protocol, no information is available that permits an evaluation of labor force behavior when using a 24-month observation period (the necessary questions are simply not asked at appropriate

APPENDIX: Descriptive Characteristics of African American and White Men[a]

	African Americans	Whites
Labor force status (percent) (wave 7)		
Full-time	32.7	35.0
Part-time	6.8	9.6
Not working	52.4	50.7
Died/institutionalized	8.0	4.7
Age (mean years)	61.5 (4.3)	61.7 (2.7)
Married (percent)	63.2	82.7
Work-limiting health condition (percent)	42.5	29.4
Income (median $)	3,000	5,585
Education (mean years)	8.6 (4.3)	11.8 (3.5)
Total (unweighted) sample size	290	3,265

[a] See text for definition of variables. Standard deviations in parentheses.

points in the survey.) Although ideally we would like to have such a measure in our model, we believe this is not a serious problem given our goals. Further, we have estimated similar models of labor force transition for these two race groups based on an eight-month observation period, which does allow for the estimation of pension eligibility. Results of a series of models that include a pension measure show that it has no effect on the other variables, regardless of whether it is in the model or not. That is, the absence of a measure of pension eligibility from the model does not change the statistical effects or the interpretation of other measures in the model. Second, measures that are included in the present analysis (e.g., age, education, and income) proxy some of the expected effects of pension eligibility.

4. We recognize that considerable heterogeneity within each labor force category may exist. For example, the not-working category includes those who are voluntarily and involuntarily not working. Similarly, the part-time worker category likely contains persons who have withdrawn from their lifetime occupations and continue to work for their own satisfaction, in addition to persons who must work to supplement their retirement income. Consequently, caution should be exercised when interpreting behavior within categories.

5. A few additional persons are categorized as disabled in subsequent waves of the sample. In the SIPP, once respondents are classified as disabled, they are not asked again about this issue. Thus, because of the design of the SIPP, it is not possible to determine whether a person recovers from such a condition. Note also that there have been several attempts to determine if self-evaluation of health or disability status differs by race (e.g., Angel & Thoits 1987; Gibson

1991b; Mutchler & Burr 1991). Although there are theoretical reasons to expect differences, research is not conclusive.

6. Results of wave-to-wave analyses of labor force status for a similar sample of men from the SIPP (not reported here) suggest that stability in labor force behavior over the two-year observation period is characteristic of about two-thirds of the sample. More than 40% of the men were classified as not in the labor force at all seven observation points (four-month reference periods), while about one-fifth of the men worked full-time for the entire period. An additional 6% of the men experienced transitions between full-time and part-time work only, neither leaving nor entering the labor force, but rather moving between full-time and part-time work. About 8% left the labor force, and about 1% entered it. About 15% experienced two or more changes in status other than changes in hours: These include retirements followed by reentries, reentries followed by reexits, or other multiple transitions. Taken as a whole, these data indicate substantial movement in levels of labor force participation during these two years. This is similar to findings reported by other researchers (see Anderson et al. 1984).

7. Researchers have noted that older African American and white men observed at a single point in time display different patterns of labor force participation, and these race groups exhibit substantial variation in expected number of years of working life (see Smith 1986; Welch 1990). An analysis of labor force status by race at wave 1 shows that African American men are less likely than similar white men to be in the labor force (results not reported here). These cross-sectional racial differences are statistically significant and comparable to findings from other data sources (U.S. Bureau of Labor Statistics 1994).

8. The coefficients for the contrasts in columns 4-6 can be generated by algebraic manipulation. However, this method of presentation makes comparisons easier.

Track Mobility in Secondary School

MAUREEN T. HALLINAN, *University of Notre Dame*

Abstract

Tracking, a pervasive organizational practice in American secondary schools, creates instructional groups that are homogeneous with respect to student ability. It is a highly controversial practice frequently criticized because it locks students into a particular track level for an entire school year or longer. This study examines several theoretical ideas about the basis of track selection and about track mobility patterns. Relying on longitudinal data from over 2,000 students, the research examines the frequency of track mobility and the direction of change in track assignments over students' four year high school careers. The data show evidence of considerably more mobility than is typically assumed. The findings relate mobility to student and school characteristics and to the curriculum. The results demonstrate how track mobility can provide differential learning opportunities to pupils, particularly females and low-income students.

Tracking, or the grouping of students by ability for instruction, occurs in most American secondary schools in both English and mathematics. A typical track structure in English consists of four levels: advanced, honors, regular, and basic. The track structure in mathematics tends to be similar, but may include a fifth level, often designated as very basic. Larger high schools may have a more elaborate hierarchy of track levels, while smaller schools may collapse some track categories.

The practice of tracking students for instruction is highly controversial. Advocates of tracking argue that the practice facilitates student learning by enabling teachers to gear their lessons to their students' ability levels. Critics claim that tracking disadvantages low-track students because the quality of instruction in the low tracks is inferior to that provided at higher level tracks and because it damages students' self esteem. Moreover, critics claim that track

 Social Forces, March 1996, 74(3):983-1002

assignments tend to be fixed across all years of high school, resulting in long-term negative consequences of initial misassignments. They also charge that permanent assignments fail to take into account the differential rates of students' cognitive development.

Research on the effects of tracking on student achievement is fairly consistent in showing positive effects of tracking on the achievement of high-tracked students, negative effects on low-tracked students, and negligible effects on those assigned to the middle or regular track (see Slavin 1990, for a review of this literature). Other studies identify factors that affect initial track assignment; show that background characteristics other than ability influence track placement; and demonstrate that schools differ in the criteria they use for assignment (Hallinan 1991, 1992). In contrast to this large body of literature on track placement and its consequences, few studies examine the permanence of track assignments (exceptions are Rosenbaum 1976; Garet, Agnew & DeLany 1987; Pallas, Natriello & Riehl 1994). Most of the cross-sectional and longitudinal studies of tracking seem to assume that no changes in students' track level occur during or across school years.

It is important to know whether track assignments tend to be permanent in order to evaluate the effectiveness of tracking as a pedagogical practice. If students are not allowed to move from one track to another, then an inappropriate early track placement could have serious consequences for a student's achievement, especially since the effects would be cumulative over a student's high school career. If, on the other hand, students are reassigned to different tracks in response to changes in their achievement or when a misplacement is detected, then tracking may facilitate student learning.

Several questions arise concerning track mobility. The most fundamental one is whether track assignments are fixed across a school year or from one school year to the next. If students change track during their high school career, does the incidence of mobility vary by school and by subject area?

Questions also arise regarding the timing of track change. When during high school do track changes typically occur? Is change more likely at the beginning of high school when teachers do not know the students well and initial placement is based primarily on objective measures of ability? Or are track changes more frequent later in high school when students have fulfilled graduation requirements and are permitted to choose more elective courses? Are reassignments more likely to occur between school years than during an academic year?

Another set of questions concerns the direction of track mobility. When students change track, are they more likely to move to a higher or a lower track? How are students' ascribed and achieved characteristics related to the likelihood of their changing to a higher or lower track? Is the probability of an upward or downward move the same for mathematics as it is for English?

Further questions concern which students change track. Are track reassignments primarily a response to students' learning needs? Are nonacademic considerations taken into account in making track reassignments? Do students' background characteristics play a role in track changes? Are student reassignments influenced by structural and organizational characteristics of schools, such as school size, instructional resources, and teacher preferences?

Finally, one may ask whether track mobility accomplishes its presumed aim, namely, to increase track homogeneity. If track reassignments are governed primarily by the desire to improve the fit between student and level of instruction, then one would expect tracks to become more homogeneous over time. On the other hand, if other factors influence track change, such as student choice, and schedule conflicts, then track mobility may have little effect on track homogeneity or may result in greater track heterogeneity.

This article provides an in-depth analysis of track mobility for a sample of secondary school students. The research will document the frequency and direction of track change; examine the individual-level determinants of track mobility; and identify the factors that affect upward and downward track mobility as well as those that influence dropping a subject in which courses are tracked. The study also will demonstrate the effects of track mobility on track homogeneity.

Conceptualizations of Track Mobility

Track selection systems have been conceptualized in a number of ways. In an early essay, Turner (1960) describes two ideal types of social mobility patterns that are useful in characterizing track change: sponsored mobility and contest mobility. In sponsored mobility, individuals are selected at an early point in their lives for elite status. They are separated from those not selected, given special preparation, and provided with access to elite positions not offered to others. Turner argues that in British schools, streaming (tracking) is described by a sponsored mobility model. The sponsored mobility model implies virtually no track mobility, since those originally selected as elite generally maintain that status while those not selected cannot attain that status themselves.

Contest mobility, in contrast, denies no one access to elite positions. Indeed, under contest mobility, less successful individuals may be given remedial help to increase their chances of competing. Separation is delayed and its consequences minimized. Contest mobility never guarantees status security since newcomers can always displace those in status positions. Turner claims that in American schools, tracking resembles a contest mobility model. The contest mobility model permits movement in either direction, tied to meritocratic criteria, while encouraging upward mobility.

Rosenbaum (1976) proposes a different model of track mobility, namely a tournament model. In a tournament, winning grants the right to go on to the next round; losing results in elimination from the contest. In a case study of tracking in a junior and senior high school, Rosenbaum identifies three characteristics of the school's tracking system: little change into or out of the upper, college track, little movement into college tracks from noncollege tracks, and considerable movement into noncollege tracks from the lower college track. Based on these results, he claims that tracking is a tournament in that once a person moves out of a college track, the opportunity to return to that track level is lost permanently. Remaining in a college track provides better opportunities to learn and sustains the hope of future success. The tournament model, therefore, predicts only downward mobility, based on meritocratic standards.

Garet, Agnew and DeLany (1987) view track mobility as a matching problem. They argue that course selection decisions are made jointly by school personnel and students. Schools determine the structure of the track system, including which courses are offered and when they are scheduled; students choose courses from among these offerings. Schools are constrained by resources while students are influenced by college aspirations, peer networks, and scheduling constraints. Matching students to courses demands compromises by both the school and the student. The process resembles an optimization problem in which the number of school and student preferences satisfied is maximized. The optimization model presupposes mobility that is somewhat random with respect to students' background characteristics and academic ability.

Hallinan and Sorensen (1986) depict track mobility as a vacancy competition. Individuals can advance to a higher position in a structure only when one becomes vacant. When a position is available, it is offered to the candidate who ranks highest on the relevant criteria. In a tracking structure, a position in a track becomes available when a student in one track moves to a higher or lower track or leaves the track structure. The opportunity to move into the vacancy is offered to the student in the next lower track who ranks highest in the ability distribution of that track. School organizational characteristics, including teacher resources, space, and norms governing teaching loads determine the initial size of the tracks while various student and school factors affect the rate of vacancies and the amount of track movement. The vacancy competition model permits upward movement, based on meritocratic criteria.

Barr and Dreeben's (1983) conceptualization of the formation of ability groups in a first grade class suggests another mechanism governing track mobility, which can be referred to as a technical model. They claim that the number, size, and composition of ability groups in an elementary school classroom are a response to distributional characteristics of the class. If, for example, a large number of students are at the low end of the ability distribution, then teachers may form two low ability groups to accommodate their needs. If the ability distribution is fairly uniform, then equal-sized ability groups are likely to be created. In this framework, a teacher moves students to different ability groups in order to accommodate their learning needs. Applied to tracking in the high school, this perspective would require that schools take into account the ability distribution of the students in predetermining track size and that they, rather than the students, make decisions regarding track changes. The technical mobility model, like the contest mobility model, allows upward or downward mobility dependent on student performance.

The models predict varying degrees of change in track homogeneity over time. The contest and technical models imply increasing homogeneity in all tracks, since movement is dependent on student achievement. The tournament model predicts increasing homogeneity in the higher tracks and decreasing homogeneity in the lower tracks since only downward movement is permitted. The models of sponsored mobility, vacancy competition, and optimization imply little change in track homogeneity at any track level.

Characteristics of Track Mobility in High School

These various mobility models depict different kinds of track movement based on different motivations. The models are based on various assumptions about the rules and regulations governing the track selection process in contemporary American high schools. Some models assume that track decisions are made by school personnel without taking student choice into account. Others assume that students have a voice in the selection process. Some models present track change primarily as an effort to create more homogeneous instructional groups. Other models assume that school authorities take into account both student ability and other student characteristics. The fit between a model's assumptions and the rules and regulations that govern tracking in a high school determines the validity of the model as a representation of track mobility.

In most contemporary high schools, while school authorities aim to create homogeneous instructional groups, they employ a number of criteria in making track assignments. They consider standardized test scores as a measure of student ability and grades as a measure of student achievement. In addition, they consider teacher recommendations that convey teacher perceptions of student motivation, effort, and academic interests. Moreover, contemporary schools typically permit some degree of student choice in track selection, allowing students to base their choices on factors such as educational and occupational aspirations, peer influences, scheduling conflicts, and time constraints.

The process of track selection and mobility in the schools in this study is described in the student manual. The same rules govern track selection in many contemporary high schools. The manual states:

> Students are guided toward placement in specific courses based on criteria related to reading ability, grade record, previously completed courses, test results, and/or recommendations of teachers and counselors. Student or parent request for placement in particular course or level of a course will be fully considered.

Some of the proposed conceptual models of track mobility fail to depict the process of track change accurately because they fail to consider the various criteria schools use in making placement decisions and may ignore student choice as a factor in the process. For example, the sponsored mobility, tournament, and vacancy competition models place primary emphasis on student ability and do not consider student choice. In contrast, the optimization model emphasizes the interaction between school and student choices while the contest mobility model permits movement in any direction, based on unspecified criteria. Consequently, the sponsored mobility, tournament, and vacancy competition models, as well as Barr and Dreeben's distributional model, are not expected to describe track mobility in high school. The contest mobility and optimization models are more likely to depict patterns of track change.

In addition to the pattern of track change described by the contest mobility and optimization models, several other features of track mobility can be anticipated. The timing of track change is likely affected by two factors. First, track changes that occur during a school year disrupt the learning process. If students move to a higher track, they must make up material not covered in the

lower track. Regardless of whether a student moves to a higher or lower track, the teacher typically must devote some instructional time to help the student adjust, thereby depriving the other students of instructional time. In addition, the social relations and the routine of the classroom may be altered. Track change that occurs between school years is less disruptive and consequently more likely than change during the school year.

The timing of track change in a student's high school career depends on several factors. The initial 9th grade track assignment is based on objective measures of ability, recommendations, and parental and student preferences (Hallinan 1991). Since high school personnel generally do not know the incoming students personally, some misassignments are likely, necessitating track changes in 9th grade to correct them. Fewer misassignments would be anticipated in the upper grades, since counselors and other school personnel would know the students better and could make more accurate placements. At the same time, the curriculum is more complex in the latter years of high school, and students have more opportunities to select different courses in different tracks. The need to correct misassignments in the early high school grades and the number of course options available to students in the later grades lead one to expect some degree of track mobility throughout high school.

Graduation requirements affect the likelihood that a student leaves the tracking structure, a departure that can come about in two ways. First, if students feel unprepared for a particular tracked course, they may take an untracked remedial course to strengthen their abilities before enrolling in the more difficult tracked course later. Second, students may choose not to take any English or mathematics courses during a given year in order to take a preferred course. In this case, if the course omitted is English, the student must make up the tracked course either in summer school or by taking two English courses in a subsequent year, in order to earn the eight English credits required for a diploma. Since only four credits of mathematics are required for graduation, students may drop out of mathematics without jeopardy after two years.

A number of factors affect the direction of track mobility. Most of the conceptual models of mobility imply that movement to a higher track is less likely than change to a lower track. Nevertheless, the role of student choice in track mobility suggests a different pattern. Students may be attracted to higher track courses because of college aspirations, parental pressure, status, teacher reputation, or the curriculum. In addition, organizational characteristics of a track system, such as the elimination of low-track mathematics courses in eleventh or twelfth grade, increase the likelihood of some students' moving to a higher track. Students also are attracted to lower-track courses to avoid failure or to lessen study time. The various motivations that govern student track selection suggest that considerable upward and downward mobility can be expected.

Empirical research on gender and race biases in education alert one to the possibility that background characteristics may exert an influence on track mobility. To the extent that females in high school are more proficient in verbal skills but have less confidence in their mathematical abilities than males, as is suggested in the literature, they are more likely to change to higher-tracked English courses and lower-tracked mathematics courses than males. If teachers

associate the typically lower standardized test scores of black students with lower motivation and effort, they are likely to encourage blacks to move to lower-level courses more frequently than whites.

Since the aim of tracking is to create homogeneous ability groups, one would expect track change to lead to greater track homogeneity over time. However, other factors influencing track change make the attainment of this goal less likely. The reliance of teachers on a number of criteria in recommending track change and the role of student choice in tracking decisions suggest that increasing track homogeneity is not an operational goal in the schools. As a result of the various factors that affect track assignments, an increase in track homogeneity as a result of track mobility is not expected.

The research presented here documents the frequency of track change in English and mathematics, the direction and timing of track mobility, the characteristics of students who change track, and the consequences of track mobility for track homogeneity.

Methodology

SAMPLE

In 1986, a longitudinal survey of tracking in middle and secondary schools was initiated. Information was obtained for all the students beginning 7th grade that year in seventeen public and private elementary and middle schools in two midwestern cities. Similar information was gathered from the following cohort of 7th grade students the next year. In 9th grade, these two cohorts of students fed into six public high schools, two Catholic schools, and one private school. One of the Catholic high schools chose not to participate in the study, and since the private high school did not track students, it was also excluded from the analyses.

The research reported here is based on data from the two cohorts of students who attended one of the six public high schools or the one Catholic high school in the sample. Information was collected on the tracking structures and policies of the high schools in the sample. These data include the number and size of tracks, track composition with respect to gender, race, ethnicity, and academic ability, and criteria for assigning students to tracks. In addition, changes in student track assignments within and across academic years were recorded.

Students' gender, race, ethnicity, age, and free- or reduced-lunch status were obtained from student records. Because only low income students qualified for the free- or reduced-lunch program, these data are used as a measure of socioeconomic status. School records provided grades in English and mathematics at the end of each semester. Standardized scores in English and mathematics from the Indiana Statewide Test of Educational Progress (ISTEP), a mandatory statewide test administered to students in the 9th and 11th grades, also were obtained from school records.

VARIABLES

The dependent variable in the analysis is track mobility. Students may move from the track to which they are initially assigned or may retain their original placement. For each student in the sample, a complete record of initial track placements and every change in those placements throughout high school are available. Track mobility is coded as change = 1 and no change = 0.

The independent variables for the analyses include gender (female = 1, male = 0), race (black = 1, white [including a small number of Asians, Hispanics and American Indians] = 0), socioeconomic status (free lunch = 1, otherwise = 0), and age (in years). Ninth grade standardized test scores in English and mathematics, coded as English 9-ISTEP and math 9-ISTEP, provide a measure of ability. Achievement is measured by student grades in English and mathematics, coded as F = 0, D = 1, C = 2, B = 3, A = 4.

No school or track-level data are missing, since these data were obtained from district and school records and from principals, teachers, and counselors. A small amount of individual-level data are missing, due primarily to missing grades. This represents less than 2% of the sample. Students who were not part of the usual tracking structure during high school are excluded from the study, including special education, learning disabled, and bilingual students. Students who transferred out of or into the schools in the sample after the beginning of 9th grade or who dropped out of high school are excluded also. The transfers and dropouts represent about 10% of the student population. While the dropouts likely have lower test scores and grades than the students in the sample, this should not affect the track analyses reported here.

METHODS OF ANALYSIS

Both descriptive and inferential analyses are conducted. In the descriptive analysis, percentage distributions and records of track assignments illustrate the frequency, direction, and duration of track change over high school.

The inferential analysis relies on logistic regression models to examine the determinants of track mobility. Three models are estimated. The first model predicts the effects of the independent variables on the probability of moving to a higher track, compared to not changing track. The second model estimates the likelihood of changing to a lower track, compared to not changing track. The third model examines the determinants of dropping out of the track sequence in English and mathematics, compared to continuing to take tracked English or mathematics courses.

Results

Characteristics of the students in the total sample of 2,394 students in English and 2,391 students in mathematics are presented in Table 1. The sample is fairly evenly divided by gender. About 16% of the students are black and 16% have low socioeconomic status (SES). On the average, the students are slightly below 15 years old in the middle of 9th grade. The average grade in English and mathematics is C+. Approximately 6% of the sample is in each of the basic and

Upward mobility in math	.07	.26	2,391	Dummy: Math track upwardly mobile = 1
Downward mobility in math	.04	.20	2,391	Dummy: Math track downwardly mobile = 1
Drop track math	.64	.48	2,391	Dummy: No English tracked class = 1

[a] The sample contains those students in the same high school or school district for grades nine through twelve and initially assigned to a 9th grade English or mathematics track.

advanced English tracks, 51% is in the regular track, and 37% is in the honors track at the beginning of 9th grade. In mathematics, 10% of the students are in the very basic track, 17% in the basic, 41% in the regular, 23% in the honors, and 9% in the advanced track.

The analyses address the following five questions: (1) How much track mobility occurs during high school? (2) When does track mobility occur? (3) Do students tend to move to higher or lower tracks, or to discontinue taking a tracked subject? (4) Who is most likely to move? (5) Does mobility increase track homogeneity?

HOW MUCH TRACK MOBILITY OCCURS?

The descriptive statistics in Table 1 show that 30% of the students (upward mobility in English + downward mobility in English) change English track during high school and 11% of the students (upward mobility in math + downward mobility in math) change mathematics track. Nineteen percent of the students complete high school at a higher English track than the one to which they were originally assigned in 9th grade, while 11% finish in a lower track, and 7% drop tracked English. In mathematics, 7% finish high school at a higher track and 4% at a lower track than they started, while 64% drop tracked mathematics.

The data reveal a considerable amount of track mobility during high school. Almost one-third of the students finish high school in a different English track than the one in which they started. Less mobility is found in mathematics, partly because stringent prerequisites for movement to upper-level courses prevent some students from moving up. Overall, the data refute the claim that tracking locks students into a track level at the beginning of high school and precludes subsequent change.

Only a small number of students drop out of tracked English courses during high school because four years of English are required for graduation. Those who drop an English course one year need to make it up in summer school or by taking two English classes in a subsequent year. A large percentage of students drop mathematics before the end of twelfth grade, likely because only two years of mathematics are required.

WHEN DO STUDENTS MOVE?

To better understand track mobility, it is necessary to determine when track changes occur. Table 2 shows that far more track mobility occurs between school years than during the year. For example, 14% of the students change English track between the beginning of 9th grade and the beginning of 10th grade, and most of this change takes place over the summer. The same pattern is found in subsequent years. Similarly, more students change mathematics track over the summer than during the school year. In other words, students tend to move to a higher or lower track after a specific course has been completed rather than while it is in progress, thereby minimizing disruption of instruction.

TABLE 2: Proportion of Students Who Change Track by Year in School[a]

End grade 11 to begin grade 12	.19	2,265	.18	1,042
Begin grade 11 to begin grade 12	.21	2,243	.24	1,029
Begin grade 12 to end grade 12	.04	2,202	.02	845

[a] The sample contains those students in Table 1 who were assigned to an English or Mathematics track at the beginning and end of any included school year.
[b] Some students changed tracks both between the beginning of 9th grade and the end of 9th grade and between the end of 9th and the beginning of 10th. Hence, the annual statistics show fewer moves than the sum of the school year and summer counts. The same is true for any short-term/long-term comparison of proportions.

At the same time, the amount of mobility that occurs during the school year is not negligible, particularly in mathematics. During 9th grade, 12% of the students in the seven schools in the sample, or 286 students, change to a different mathematics track. Depending on whether these changes result in better placement, they may or may not be educationally beneficial either to the student who moves or to the student's peers.

A second pattern in the timing of track mobility is that more change occurs later in students' high school careers than earlier. Table 2 shows that in English, 21% of the students change track between 11th and 12th grade, compared to only 14% between 9th and 10th, and 13% between 10th and 11th. In mathematics, about 24% of the students change track between 11th and 12th grades, compared to considerably smaller percentages between 9th and 10th grades (23%) and between 10th and 11th grades (21%).

The pattern of greater track change in the upper grades is due to several factors. First, students can no longer take very basic mathematics after 10th

grade, or basic mathematics after 11th grade. Second, while students in lower grades take mostly required courses, those in upper grades take a number of electives that may conflict with tracked mathematics and English courses, leading them to change those courses. Finally, since older students are more likely to work after school, those in upper tracks may select easier courses to avoid having to spend long periods of time on homework.

WHERE DO STUDENTS MOVE?

Critical to understanding the nature of tracking is a determination of where students go when they change track. Table 1 shows that students in the English track moved mostly within the track structure and students in the mathematics moved mostly out of the track structure. The data (not presented) show that about two-thirds of the students who remain in tracked English and mathematics classes finish high school in a higher track than they started in, while one-third complete high school in a lower track.

One other move is possible within the track structure. Students may change to a higher or lower track during high school and later return to their original track. Since this is a somewhat small sample of students, it permits an examination of the direction and duration of these track changes. The data (not presented) reveal that most of the students remain out of their originally assigned track for only one or two semesters. For example, 18 students originally assigned to the regular English track move down to the basic track for one semester and nine more move down to the basic track for two semesters before returning to the regular track. The remaining six students who move down from the regular track continue in the basic track for a longer period of time. Similarly, of the 123 students who move up one or more tracks in English, most move from the regular track to the honors track for only one or two semesters.

A similar tendency toward short-term change is found in mathematics. Fourteen of the 39 students who move from the honors to the regular track return to the honors track after one or two semesters. Fourteen other students who make this change remain in the honors track for five semesters. However, 13 of these students are from school 2.1, suggesting the occurrence of an idiosyncratic school change. The most common upward change in mathematics is from the regular track to the honors track. Of the 129 students who change to a higher mathematics track, 66 students move from the regular to the honors track for one or two semesters and then return to the regular track. The short-term nature of most of these track changes suggests that students are exploring different track levels but finding that their initial placement was appropriate.

WHO MOVES?

To identify the predictors of track mobility, two logistic models are estimated: a model comparing change to a higher track to no change and a model comparing change to a lower track to no change.

Table 3.1 presents the estimates of a logistic model that predicts the likelihood of moving to a higher track as opposed to not changing track, on the basis of student characteristics, track level, and school. The results show that

+ $p < .10$ * $p < .05$ ** $p < .01$

older students are less likely to move to a higher English track than younger students. Students who have higher standardized test scores and grades in English are more likely to move to a higher track.

In addition, students initially assigned to the basic track are more likely to move to a higher track compared to those in the regular track, while students in the honors track are less likely to move up than those in the regular track. Those in the advanced track are excluded from this analysis because they cannot move to a higher track. Students in schools 1.3, 2.1, and 3.1 are signifi-

cantly less likely to move to a higher track than those in school 1.1, while schools 1.4 and 1.5 show a similar though weaker tendency. The greater tendency of students in school 1.1 to be upwardly mobile in English is interesting because this school has the strongest academic reputation among the public schools in the sample. It is likely that a strong academic climate motivates upward track mobility.

In mathematics, the model shows that females are less likely to move to a higher mathematics track than males. Higher ISTEP scores and course grades are associated with greater upward change. Students in the regular track are more likely to move up than those in the honors track. Basic track students are excluded from the analysis because they must move up or out for structural reasons since the basic track is eliminated after 11th grade. Those in the advanced track are excluded because they cannot move to a higher track. Students who attend schools 1.2 and 1.3 are less likely to move to a higher track than those in school 1.1.

These results show that strong performance leads to upward track mobility. However, this effect is constrained by track placement. Controlling for ability and achievement, we find that students assigned to a lower track are more likely to move to a higher track than their peers in higher tracks.

Table 3.2 shows the predictors of moving down one or more tracks compared to not changing tracks. Students are more likely to move to a lower English track if they are male, have low income, low standardized test scores and grades, or are in the honors or advanced tracks, compared to the regular track. Students in schools 1.2 and 3.1 are significantly more likely to move to a lower track than those in school 1.1. In mathematics, low standardized test scores and low grades lead to a downward track change. Students who attend school 2.1 are significantly less likely to move to a lower track in mathematics than those in school 1.1.

In general, weak performance predicts downward track mobility. However, as with upward mobility, track level also has a direct effect on downward mobility. Assignment to a higher track increases the likelihood of moving to a lower track, regardless of ability and achievement.

These analyses reveal that student background, ability, and achievement affect track mobility. Moreover, track assignment exerts an independent effect on the likelihood of a track change and the direction of the change. As a strong predictor of track mobility, track placement plays a crucial role in providing students with opportunities to learn.

Since a considerable number of students discontinue taking both English and mathematics during high school, a third logistic model examines the determinants of dropping out of a tracked English or mathematics course sequence. This analysis permits a comparison of the factors that affect upward and downward track mobility in English and mathematics with the predictors of discontinuation in these subjects.

Table 4 presents the determinants of dropping out of the English or mathematics track sequence. The parameter estimates show that females, those with lower grades, and, to a lesser extent, low-SES students are more likely to drop English. Moreover, students in the basic track are more likely to drop English compared to those in the regular track, while those in the higher tracks

are less likely to drop it. A school effect is observed also; students in schools 1.2, 1.4, 1.5, and 2.1 show a stronger tendency to drop English than those in school 1.1.

Females, older students, and low-SES students are more likely to drop mathematics than their peers. Whites are slightly more likely to drop mathematics than blacks, as are students with low test scores and grades. Pupils in schools 1.2 and 3.1 are less likely to drop mathematics than those in school 1.1. These findings show that poor performance increases the likelihood of dropping

N	1,676		1,486	

[a] A negative coefficient indicates a greater likelihood of changing track versus not changing track.

+ $p < .10$ * $p < .05$ ** $p < .01$

out of the mathematics track structure. Assignment to a lower track also increases the likelihood of dropping out of tracked mathematics courses, regardless of ability and achievement.

Comparing the determinants of track mobility in English and mathematics with the factors that affect dropping these subjects shows that lower grades and test scores are the strongest predictors of both moving to a lower track and dropping a tracked subject. In examining the influence of ascribed characteristics on course choices, the data show that females are less likely than males to move

to a higher mathematics track, and, although they are less likely to move to a lower track, they are significantly more likely to drop mathematics. Race has little effect on track mobility but whites are slightly more likely than blacks to drop mathematics. Older students are less likely to move to a higher English track and more likely to drop mathematics. Low-income students are slightly less likely to change to a higher-English track, more likely to change to a lower-English track, and more likely to drop English and mathematics than older students.

In general, the comparisons show that ascribed characteristics affect dropping out of a tracked course sequence in the same way they influence track mobility. Hence, being female, older, and having a low income appear to place students at risk for changing to lower tracks and dropping out of tracked subjects. In this way, tracking can be seen as a mechanism through which fewer opportunities for learning are channeled to these students.

DOES TRACK MOBILITY INCREASE TRACK HOMOGENEITY?

If track changes are governed primarily by an effort to improve the fit between a student's learning ability and the level of instruction provided at a particular track level, then mobility should result in increased track homogeneity. Table 5 presents the standard deviations of the ISTEP scores of the students at the beginning and end of each year in high school by track and subject for school 1.1. This school was chosen for illustration because it serves as the comparison case in the logistic analyses. The results are similar for all the other schools in the sample, including the private school.

The data in Table 5 show little change in track homogeneity in English or mathematics over the school year at any track level. Some exceptions are when the size of a small track changes, as in basic English 11, or when there is a considerable change in the size of a large track, as in advanced math 9. In these two cases, track homogeneity increases markedly. A more impressive example is basic math 9 where track homogeneity increases after fourteen new students are added to the track. In general, student mobility has little effect on the distribution of achievement in a track. Clearly, mobility is not being used in a systematic way by the schools to increase track homogeneity. This is likely due, to a large degree, to permitting student choice to play a significant role in track selection and change.

Conclusions

The pattern of track change observed in this study suggests that track mobility in American high schools has some of the characteristics of a contest mobility model. Students moved to both higher and lower tracks, but moved to higher tracks with somewhat greater frequency. Only the most advanced tracks had strict prerequisites that limited admission. The upward bias is evidence that organizational constraints on mobility play only a small role in track change and that lower-track students may be given special assistance in moving to higher tracks. The fact that students participate in the track selection process requires a modification of the contest mobility model as a description of track mobility.

Since schools must consider the preferences of the entire student body and match them to course offerings, compromises must be made by both school personnel and students. This matching superimposes an optimization process on the mobility patterns. Track mobility in the schools examined in this study can best be described as a process that allows fairly unrestricted movement across tracks, constrained by the general goal of maintaining somewhat homogeneous instructional groups and by the desire to satisfy the preferences of as many teachers and students as possible. That is, track change resembles a contest mobility model constrained by efforts to optimize choices.

A major conclusion of this study is that track mobility occurs more frequently in high school than is generally believed. Students changed tracks in English more than in mathematics, likely because of stricter course prerequisites limiting upward mobility in mathematics. Most of the track changes in both English and mathematics occurred in the later grades, although a substantial number of students moved during 9th and 10th grades as well.

Some of the observed track changes undoubtedly can be attributed to efforts by school personnel to create a better fit between student ability and course content. School authorities make track decisions based on measures of student ability and judgments about student motivation. Several additional bases for track mobility are introduced when students participate in the decision process, some of which may be unrelated to academic considerations. The data presented here show that track changes do not necessarily result in more homogeneous tracks over time. To increase the effectiveness of track mobility in creating more homogeneous tracks, nonacademic motivations for track change need to be minimized. Further, it may be necessary for counselors to retain primary decision making power in approving track changes.

The study reveals gender, race, and income effects on track changes. Patterns of track mobility show that females are less likely to move to a higher mathematics track than males, while males have likely to change to a lower English track than females. Black students are more likely to drop mathematics than whites. Low-income students are more likely to move to a lower English track or to drop English or mathematics than higher-income students. These findings point to the need for close scrutiny of decisions governing track change to insure that track decisions channel equal opportunities for learning to students who differ in background characteristics.

In general, this study provides convincing evidence that track assignments are not fixed, as commonly believed. A surprising amount of track change occurs during each year of high school. At the same time, the patterns of track mobility observed in this study reveal a different source of inequity associated with tracking, namely an effect of background on the direction of track change. Schools must exercise considerable care in monitoring tracking assignments to avoid a relationship between student social characteristics and track decisions. Track mobility is a complex process that can have powerful, though often unrecognized, effects on student learning.

Conservative Protestantism and the Parental Use of Corporal Punishment*

Abstract

The present study develops arguments linking Conservative Protestant affiliation and conservative beliefs about the Bible with the frequency with which physical punishment is used to discipline toddlers and preschoolers (ages 1-4) and older children (ages 5-11) and explores these ideas using data from the 1987-88 National Survey of Families and Households (NSFH). Multivariate results generally confirm that parents with conservative scriptural beliefs use corporal punishment more frequently than parents with less conservative theological views. Some modest net effects of Conservative Protestant affiliation are also observed. The study identifies several promising directions for future research on religious variations in child discipline.

The use of corporal punishment to discipline children has been the focus of perennial popular and academic controversy (see Larzelere 1994; Straus 1994a, 1994b). Although physical punishment is strongly supported and widely used by American parents (Straus & Gelles 1986; Wauchope & Straus 1990), critics claim that corporal punishment trains children in violence (1) by teaching that it is appropriate for powerful persons to subordinate others by using physical force, (2) by teaching that feelings of frustration and anger justify the use of violence, and (3) by establishing an association in a youngster's mind between love and violence (Gray 1988; Maurer 1974; Straus 1991). Consistent with such arguments, some research indicates that children subjected to corporal punishment tend to be more aggressive with peers and others than children who experience alternative forms of discipline (Hotaling, Straus & Lincoln 1990; Straus 1991). There is also evidence that persons who are spanked or slapped frequently in childhood may be more likely to use corporal punishment and to

 Social Forces, March 1996, 74(3):1003-1028

engage in harsh parenting and domestic abuse as adults (Egeland, Jacobvitz & Papatola 1987; Simons et al. 1991; Simons et al. 1993). In addition, even mild to moderate corporal punishment can sometimes cause serious physical injuries to young children (Taylor & Maurer 1985), and incidents that begin as mild punishment can escalate into abusive encounters. Further, some researchers have related harsh forms of physical punishment to negative developmental outcomes, including delinquency, psychopathology, academic failure, substance abuse, and others (Eckenrode, Laird & Doris 1993; Maccoby & Martin 1983; Wolfe 1987). Indeed, some studies suggest that the experience of corporal punishment even inclines children toward criminal violence in adulthood (Straus 1991; Widom 1989).

Given these and other concerns, researchers have worked to identify the social antecedents of corporal punishment. For instance, many have hypothesized (1) that working-class parents support and use corporal punishment more than their middle- and upper-class counterparts (e.g., Bronfenbrenner 1958), and (2) that African American parents support and use corporal punishment more than their white counterparts (e.g., Alvy 1987). To date, however, the empirical evidence on both points remains decidedly mixed (Cazenave & Straus 1990; Duvall & Booth 1979; Erlanger 1974).

Until recently, one important source of cultural support for corporal punishment received short shrift from researchers: *religion*. In an early exception to this general pattern of neglect, Erlanger (1974) analyzed retrospective data collected in the 1960s, and he noted that Baptists (1) were more likely to report that they had been spanked often as children, and (2) as adults, were more likely to approve of spanking in general than other respondents. Although these religious differences were substantial in magnitude, they received only brief discussion in that study — which was devoted mainly to social class differences in corporal punishment — and they were largely ignored by subsequent researchers.

Since the publication of Erlanger's (1974) article, several studies have renewed scholarly focus on religious variations in attitudes toward corporal punishment, with particular attention to the distinctive views of Conservative Protestants.[1] For instance, analyzing data on a nonrandom sample of church members from portions of Kentucky and Ohio, Wiehe (1990) reported that individuals affiliated with Conservative Protestant churches are more likely to view corporal punishment as an appropriate response to child misbehavior than are members of more liberal religious groups. Although Wiehe did not gauge the theological beliefs of his respondents directly, he argued that the churches that he classified as conservative also tend to endorse literalist or inerrantist views of the Bible, and he suggested that these beliefs contribute to pro-corporal punishment attitudes.

Following a similar line of argument, Grasmick and colleagues (Grasmick, Bursik & Kimpel 1991; Grasmick, Morgan & Kennedy 1992) used data on samples of Oklahoma City adults to show that members of Conservative Protestant denominations are especially inclined to favor corporal punishment in homes and schools. In one of these studies, Grasmick, Bursik, and Kimpel (1991) examined the scriptural beliefs of their respondents directly, and they concluded that high levels of Conservative Protestant support for corporal

punishment are largely accounted for by the tendency of Conservative Protestants to embrace literalist interpretations of the Bible.

Analyzing data from the 1988 General Social Surveys, Ellison and Sherkat (1993a) also reported that the members of Conservative Protestant denominations supported corporal punishment more strongly than other Americans. Moreover, they found that the relationship between Conservative Protestant denominational affiliation and support for corporal punishment is mediated by three key theological tenets: (1) the belief that the Bible should be interpreted as the literal Word of God; (2) the belief that human nature is fundamentally sinful and corrupt; and (3) the belief that persons who violate God's rules must be punished. In another study, Ellison and Sherkat (1993b) showed that this complex of theological beliefs also accounts for the disproportionate Conservative Protestant support for "authority-minded" parental values — i.e., the tendency to emphasize obedience in child rearing.

Although these recent investigations have shed new light on a neglected topic, they focus exclusively on *attitudes* toward corporal punishment among the general public. Consequently, they provide no direct evidence that Conservative Protestant parents themselves actually *use* physical discipline more often than other parents. Our study augments the literature in this area in several ways. We begin by reviewing "insider documents" on the topic — popular child-rearing manuals by conservative religious commentators — to develop a series of theoretical arguments linking Conservative Protestantism with corporal punishment. We then explore these ideas using data from the 1987-88 National Survey of Families and Households (hereafter NSFH). Our work centers on the parents of toddlers and preschoolers (children aged 1-4), and the parents of grade school-aged children (children aged 5-11). We consider the influence of several sets of factors — Conservative Protestant affiliation and conservative theology, parental and household characteristics, child characteristics and behaviors, and parental child-rearing values — on the frequency with which parents use corporal punishment to discipline specific children. In the concluding section of the article, we discuss several promising directions for future research on the links between Conservative Protestantism and child discipline.

Conservative Protestant Theology and Child Discipline

Why might Conservative Protestant parents use corporal punishment more frequently than other parents? Following the methodological counsel of McNamara (1985), we turn to an understudied set of insider documents, the substantial body of popular child-rearing manuals produced and distributed primarily within Conservative Protestant communities since the late 1960s (for details on this literature, see Bartkowski & Ellison 1995). Best-selling contributors to this literature include such conservative luminaries as James Dobson (1970, 1976, 1987), founder of the Focus on the Family organization, Beverly LaHaye (1977), founder of Concerned Women for America, noted conservative Christian radio television evangelist Chuck Swindoll (1991), and Marlin Maddoux (1992), president of the USA Radio Network, among many others.[2]

A careful review of these popular Conservative Protestant manuals reveals a clear and generally coherent theological rationale underlying support for the

corporal punishment of children (see Ellison & Bartkowski 1996; Ellison & Sherkat 1993a). Conservative religious beliefs about the right and responsibility of parents to discipline children with physical force commonly begin with the view that the Bible is the inerrant Word of God, the ultimate source of authority and guidance regarding every aspect of human life, including child rearing (Dobson 1970:197 and 1976:234-35; Fugate 1980:262-63; LaHaye 1977:145). Religious scripture is widely regarded as purposive divine communication with humanity, and therefore it is often presumed to contain reliable and sufficient information to guide the conduct of all human affairs. However, the implications of the doctrine of inerrancy for families, politics, and other human endeavors are perennially contested among Conservative Protestants (e.g., Barnhart 1993; Lindsell 1976). The theological and social meanings associated with biblical inerrancy are debated, produced, and disseminated by way of interpretive communities, or loose networks of theologians, pastors, and elite laity who share fundamental assumptions about the text (see Boone 1989).

The doctrine of biblical inerrancy is crucial for several reasons. First, contemporary constructions of inerrancy typically emphasize the ubiquity and divinely ordained nature of spiritual and worldly authority relations and articulate the principle that Christians should submit themselves to the leadership of duly constituted authorities in every area of life — church, family, school, workplace, and government (Ammerman 1987; McNamara 1985; Rose 1988). However, perhaps nowhere is this "authority-mindedness" (Wald, Owen & Hill 1989) clearer than in the popular literature on child rearing and family life. According to Conservative Protestant authors, families are characterized by specific patterns of authority relations (superordinate and subordinate roles) that should always remain unchallenged (Bartkowski & Ellison 1995).

The primary responsibility of children is to obey parental directives; in turn, parents are admonished to fulfill their obligations as authority figures rather than abrogating their leadership role within the family (see Christenson 1970; Fugate 1980). In support of these views, Conservative Protestant commentators marshal an impressive array of scriptural passages in which children are expected to honor and obey parental authority (Exodus 20:12; Ephesians 6:1-2; 1 Timothy 3:4-5), under threat of divine judgment (Exodus 21:15-17; Deuteronomy 21:18-21; Proverbs 30:17).

In addition to this preoccupation with themes of hierarchy and authority relations, contemporary constructions of biblical inerrancy draw heavily on Old Testament passages to emphasize themes of human sin and punishment (see Ellison & Sherkat 1993a, 1993b). Conservative Protestant commentators on child rearing argue that all individuals are born sinful (Psalms 51:5, 58:3) — that is, predisposed toward selfish conduct and inclined to reject authority in all forms (Christenson 1970:95-98; LaHaye 1977:3; Maddoux 1992:19-20).[3] For instance, Chuck Swindoll (1991) encourages parents to combat the "foolishness . . . bound up in the heart of a child" (Proverbs 22:15) with "diligent discipline" (Proverbs 13:24):

> "Foolishness" sounds rather mischievous and impish . . . somewhat lighthearted and fun-loving. But the Hebrews saw it as far more serious. "The fool has said in his heart 'There is no God'" (Psalm 14:1). The "foolish" possess a God-mocking, instruction-hating nature. Fools, therefore, despise discipline. Foolishness has a disrespect for authority.

Determined to go its own way, it resists all reproof. And remember, all this "is bound up in the heart of a child" — *your* child (88, emphasis in original).

Beverly LaHaye (1977) sounds an even shriller alarm:

[God] gave each of us a free will to choose evil or good, and the child that is not trained to choose good will undoubtedly choose evil. . . . It is of great benefit to the parent when he realizes that it is natural for his child to have a desire for evil. The child is not just being obstinate and uncooperative but is following that natural desire to learn more about and to experience *evil* (3, emphasis in original).

According to Conservative Protestant parenting specialists, "willful defiance" is virtually inevitable among children, particularly toddlers, and such defiance carries dangerous long-term consequences if unchecked. They believe that without appropriate discipline, children will grow up lacking respect for parents and other authority figures, nurturing rebellious tendencies that will make them unfit citizens, unproductive workers, and unhappy spouses and parents (Christenson 1970:88-90; Dobson 1970:14; Fugate 1980:14-15; LaHaye 1977:2).

Although Conservative Protestant child-rearing specialists extol the value of stern discipline — and particularly corporal punishment — on instrumental or pragmatic grounds, for securing behavioral conformity and training children for adulthood, most also believe that this form of punishment conveys an important religious lesson to youngsters about the nature of God. In brief, they argue that parents symbolize God's authority to children, and that many children come to conceptualize or envision God, and to understand their relationship to God, through parental imagery (e.g., LaHaye 1977:69; Swindoll 1991:95). Consequently, these commentators conclude that while parents must teach their children by example that God is kind and loving, it is equally important to communicate by example the swift and uncompromising nature of divine punishment (Christenson 1970:99-100; Dobson 1976:171-72; Fugate 1980:41-42).

A crucial part of the Conservative Protestant rationale for firm child discipline involves the imperative of conversion (Ellison & Sherkat 1993a; Greven 1977). If the sinful tendencies of youngsters go unchecked, their very souls are believed to be in jeopardy. Many Conservative Protestants fear that if children have not been trained to submit to worldly authority figures, they will also be unable or unwilling to submit themselves to God's supreme authority and guidance, a key requisite of salvation (Daugherty 1991:72; Fugate 1980:190; LaHaye 1977:132). These eternal implications of child discipline are underscored vividly by Dobson (1976:172-73):

If a little child is taught to disrespect the authority of his parents, systematically from the tender years of childhood — to mock their leadership, to "sass" them and disobey their instructions, to exercise extreme self-will from the earliest moments of awareness — then it is most unlikely that this same child will turn his face up to God, about twenty years later, and say humbly, "Here I am, Lord; send me!" To repeat, *a child learns to yield to the authority of God by first learning to submit (rather than bargain) to the leadership of his parents.* (emphasis added)

Given such distinctive and strongly held views on sin and its consequences, religious conservatives stress the urgent need for parents to begin "shaping the

wills" of their children at an early age. Virtually all Conservative Protestant writers agree that Christian parents are morally obligated to use physical "chastisement" with the "rod" because this is the primary biblically ordained response to overt challenges to parental authority (Daugherty 1991:67-68; LaHaye 1977:145-47; Lessin 1979:24; Swindoll 1991:85-88). In support of this claim, they refer to numerous scriptural passages that they interpret as encouraging the use of physical force to shape the will of children (2 Samuel 7:14; Proverbs 23:13-14, 29:15; Hebrews 12:6-8; see Greven 1990:52-55 for an alternative reading of these passages).

Although there is broad consensus among Conservative Protestant parenting writers that corporal punishment is a necessary and important part of child rearing, it bears mentioning that there is less agreement on other issues. For instance, a few writers countenance the expansive use of corporal punishment for virtually any offense, reasoning that most disciplinary infractions ultimately constitute disobedience of one sort or another (e.g., Fabrizio 1969), and some decline to rule out the use of physical punishment to discipline children of almost any age, including adolescents (e.g., Fugate 1980). However, the most prominent conservative religious writers (Dobson 1976, 1987; Swindoll 1991) advocate corporal punishment primarily if not exclusively to confront willful defiance, mainly by toddlers. Dobson (1976, 1987) also suggests that the frequency of physical punishments should diminish as children grow older and develop appropriate internal behavioral controls, and he explicitly discourages parents from spanking or slapping adolescents.

Many Conservative Protestant writers also endorse nonphysical disciplinary strategies, including positive reinforcement, to build a child's self-esteem and maximize compliance (Dobson 1976:78; LaHaye 1977:141-42; Swindoll 1991:104-5), natural or logical consequences as punishment for childish irresponsibility (e.g., Dobson 1976:32), and other techniques.

The foregoing review of popular Conservative Protestant child-rearing literature suggests several guiding hypotheses regarding religious differences in the physical punishment of children. First, because conservative church communities are likely to encourage and support the use of "traditional" parenting practices by their members, we expect that members of Conservative Protestant denominations will use corporal punishment more often than other American parents. Second, given the arguments developed above, we expect that theological conservatism — especially belief that the Bible is inerrant and should guide all human affairs — will be positively associated with the frequency of corporal punishment and that the estimated net effects of denominational affiliation will be mediated via theological conservatism.

Third, given the concern over human sinfulness among many religious conservatives, it is possible that the links between Conservative Protestantism and physical punishment will be partly mediated via parents' assessments of child behavioral patterns. Fourth, in light of the focus on intergenerational hierarchy in conservative religious child-rearing manuals, we expect that the links between indicators of Conservative Protestantism (both affiliation and theological conservatism) and corporal punishment will be partly mediated via parental values that emphasize children's obedience. The remainder of this article designs and executes an empirical test of these hypotheses.

Data and Measures

DATA

To explore the relationships between Conservative Protestantism and the parental use of corporal punishment to discipline toddlers and preschoolers (ages 1-4) and grade school-aged children (ages 5-11), we analyze data from the NSFH. Directed by sociologists at the University of Wisconsin-Madison during 1987-88 (for details, see Sweet, Bumpass & Call 1988), the NSFH is a cross-sectional national probability sample of 13,017 men and women 19 years old and over. This includes oversamples of blacks, Puerto Ricans and Mexican Americans, single-parent families, families with stepchildren, cohabiting couples, and recently married persons.

The NSFH data are ideal for the purposes at hand, and superior to the data used in most prior studies, for several reasons. First, findings from a large national probability sample are more reliable and generalizable than findings from smaller community samples or from convenience samples. Second, the NSFH data set includes information on the Conservative Protestant denominational ties and scriptural beliefs of primary parental respondents, along with extensive information on other parental and household characteristics. Third, the NSFH instrument includes a series of questions about focal children who were selected at random from the roster of household members. By using data on these focal children, we are able to investigate the frequency with which corporal punishment is used to discipline particular youngsters. Further, the NSFH permits us to consider *weekly* frequencies rather than the less precise *annual* or *lifetime* measures that are sometimes used in research on this topic.

Moreover, we are also able to consider the effects of various child characteristics and behaviors on the frequency of corporal punishment. Our analyses are restricted to the primary responding parents of focal toddlers and preschoolers and focal grade school-aged children. These analyses are presented sequentially. Data are weighted to account for the differential probability of selection in both the sample and the household, as well as biases in response rates.

DEPENDENT VARIABLE: FREQUENCY OF CORPORAL PUNISHMENT

The parents of focal children were asked the following questions: "Sometimes children behave well and sometimes they don't. Have you had to spank [FOCAL CHILD] when [he/she] behaved badly in the past week?" Those who responded affirmatively were then asked "About how many times have you had to spank [FOCAL CHILD] in the past week?" Consistent with the findings of previous research (e.g., Wauchope & Straus 1990), corporal punishment is employed more frequently on toddlers and preschoolers than on older children. Roughly 52% of the parents of focal children aged 1-4 reported using corporal punishment during the week prior to the interview, with 20% spanking their child once. To reduce skewness, we truncate this variable so that the highest response category is "six or more" spankings per week; approximately 6% of the parental respondents reported using corporal punishment this frequently. In the analyses that follow, we use ordinary least squares (OLS) regression

techniques to estimate the effects of religious variables and covariates on this outcome measure.

Among the parents of grade school-aged children, some 23% of the parents reported using corporal punishment during the week prior to the NSFH interview. Most of these parents (18% of the total) spanked once. Given the radically skewed distribution of these responses, we construct a dichotomous variable to distinguish those parents who used corporal punishment from those who did not. Because the limitations of OLS regression techniques for modeling dichotomous outcomes are well known, we use logistic regression, in which the dependent variable is the natural log of the odds of a given response category (e.g., spanking versus not spanking) (Aldrich & Nelson 1984).

KEY INDEPENDENT VARIABLES: CONSERVATIVE PROTESTANTISM

A dummy variable is used to identify persons affiliated with Conservative Protestant churches, including the following groups: Southern Baptist, Independent Baptist, other fundamentalist Baptist (Primitive, Foursquare Gospel, etc.), Church of Christ, Church of God, Independent or Open Bible churches, Adventist, Alliance Church, Church of God in Christ, Assemblies of God, Pentecostal, Holiness, Apostolic, and other fundamentalist or evangelical churches.[4]

Theological Conservatism

To measure the types of beliefs regarding religious scripture that were discussed earlier, we use a two-item index (r = .73, p < .001, Cronbach's alpha=.85) based on respondents' agreement with the following statements: (1) "The Bible is God's word and everything happened or will happen exactly as it says." (2) "The Bible is the answer to all important human problems." Responses to each item range from (1) "strongly disagree" to (5) "strongly agree," and the mean score is used as our indicator of *theological conservatism.*[5]

CONTROL VARIABLES

Child Behaviors

Our analyses include several variables tapping parental reports of the frequency with which the focal child exhibited various types of behaviors, moods, and demeanors during the three months prior to the NSFH interview. Primary responding parents of focal children aged 1-4 were read a list of ten such behaviors, including (1) "Is *fussy* or irritable"; (2) "*Loses temper* easily"; (3) "*Bullies,* or is cruel or mean to others"; and (4) *Obeys* or "does what you ask." For each statement, response categories were (1) "not true," (2) "sometimes true," and (3) "often true."[6] Primary responding parents of older children were read a similar list of behaviors (with identical response categories), except that "fussy or irritable" was not included on their list. In preliminary analyses, we explored the association between the other child behaviors on these lists (e.g., "feels sad or depressed," "feels fearful or anxious," "gets along well with others," "tries new things") and the frequency with which children are

subjected to corporal punishment. We detected no relationships between these additional child behaviors and the frequency of corporal punishment.

Authority-Minded Parental Values

To gauge parents' valuation of obedience by their children, we used a two-item index. As part of a larger battery of traits, parents were asked how important it is for their children to "always follow family rules" and to "always do what you ask." Response categories range from (1) "not at all important" to (7) "extremely important." We note that these parental values items differ somewhat from those used in many previous studies (Alwin 1984; Ellison & Sherkat 1993b), in which respondents were asked to rank the importance of a series of child characteristics. The two items identified above are combined into an index ($r = .55$, $p < .001$, Cronbach's $\alpha = .71$), and the mean score is our indicator of *authority-minded parental values.*

Respondent and Household Characteristics

We can have confidence in our findings on the relationships between Conservative Protestantism and the use of corporal punishment by primary parental respondents only when we have controlled for the potentially confounding effects of a range of sociodemographic and background factors, including the following: *age* of respondent (in years); gender of respondent (1 = *female*); race/ethnicity of parent (1 = *black*, 1 = *Hispanic*, 0 = white/Anglo); total *household income* (in tens of thousands of 1986 dollars, logged); parent's *education* (in years); number of *children younger than 5* in the household (besides the focal preschooler); number of *children aged 5 and older* in the household (besides the focal child); and the primary parental respondent's marital status (1 = *single* parent).[7]

Child Characteristics

In addition, we also include dummy variables to identify the child's sex (1 = *female* child), as well as to indicate whether the focal child is a stepchild (1 = *stepchild*) or an adopted child (1 = *adopted*). In the analyses of focal toddlers and preschoolers, we use dummy variables to identify the child's age (1 = *age* 4, 1 = *age 3*, 1 = *age 1*, 0 = *age* 2), because preliminary analyses indicated that the estimated effects of age on the frequency of corporal punishment is curvilinear for children of this age group. We also investigated the association between age and corporal punishment for older children and found the relationship to be generally linear. Therefore we include a linear *age* effect in the models for grade school-aged children. Means and standard deviations of the variables used in the final analyses are displayed in Table 1.

A NOTE ON MISSING DATA

As a rule, valid sample means are substituted for missing values on most predictor variables in order to maximize the effective sample size. Ancillary analyses show that this mean substitution procedure does not significantly alter our results. Because a relatively large proportion of NSFH respondents

TABLE 1: Descriptive Statistics on All Variables[a]

	Children Aged 1-4	Children Aged 5-11
Dependent variables

Children aged 5-18	.49 (.81)	.88 (.93)

(approximately 16%) were missing valid information on household income, a dummy variable was included in preliminary models to identify respondents who were initially missing income data. When this variable was consistently unrelated to the frequency of corporal punishment of children of either age group, it was dropped from subsequent models.

Findings

THE CORPORAL PUNISHMENT OF CHILDREN AGES 1-4

Table 2 presents the results of a series of OLS regression models estimating the net effects of Conservative Protestant denominational ties and conservative Bible beliefs on the frequency with which parental respondents physically punish focal children 1-4 years old. The models are organized in hierarchical fashion; they are designed to take into account (1) the possible confounding effects of various sociodemographic and household background factors and (2) the possible mediating effects of focal child characteristics and parental child-rearing values. Model 1 includes Conservative Protestant religious affiliation, along with controls for sociodemographic characteristics of the household, focal child, and

primary parental respondent. Theological conservatism is added in model 2. In model 3, indicators of positive and negative child behaviors are added, and authority-minded child-rearing values are included in the final model (model 4).

Several findings are especially important. In model 1, Conservative Protestant denominational affiliation emerges as a weak ($p < .06$) positive predictor of the frequency of corporal punishment, even net of the potentially confounding effects of various household, respondent, and child characteristics. As expected, this estimated net effect is completely attenuated with the inclusion of theological conservatism in model 2. It is noteworthy (1) that the estimated net effect of theological conservatism is greater than that of Conservative Protestantism, and (2) that the addition of theological conservatism significantly enhances the predictive power of the model. These empirical patterns indicate that while

members of Conservative Protestant groups embrace disproportionately conservative views about the Bible and related issues, these beliefs are also held to a lesser degree by members of other religious communities.

Theological conservatism remains a significant predictor in models 3 and 4 with minimal change in the size of the parameter estimate, despite the addition of statistical controls for child behaviors and parental child-rearing values. Thus, it appears that despite their sensitivity to issues of sin and punishment, Conservative Protestant parents are no more likely than other parents to evaluate the behavior of their children in *globally* negative terms — as disobedient, temperamental, and so forth. Further, although parents' theological conservatism is positively associated with valuation of obedience and self-control in children ($r = .34$, $p < .001$), the addition of controls for such authority-minded parental values reduces the estimated net effect of theological conservatism only slightly.[8]

As is frequently the case with survey research, the size of the parameter estimates for religious variables is not overwhelming, and their unique contribution to the overall explanatory power of the models appears relatively modest, approximately 2-3%. However, given the widespread concern about the social antecedents and consequences of corporal punishment among academic and popular experts, our results may have important implications. According to the estimated full model (model 4), each increment in the theological conservatism index of the respondent is associated with an increase of .221 in weekly spankings administered to the focal child aged 1-4. On average, then, a parent with the maximum score of 5 on the theological conservatism index — that is, one who strongly agrees that the Bible is inerrant and contains answers to all human problems — spanks or slaps his or her toddler or preschooler .884 more times per week on average than a theologically liberal parent who receives a score of 1 and strongly disagrees with these scriptural views. To be sure, it is important not to reify these parameter estimates. Nevertheless, assuming a generally constant average rate of physical punishment by parents, these estimates translate into a difference of nearly 50 episodes (.221 x [5-1] x 52 = 45.698) of physical force over the course of a 12-month (52-week) period.[9]

In addition to examining the main effects of religious variables, we also included various cross-product (interaction) terms in model 4 of Table 2 to investigate several contingent relationships. For instance, we examined the possibility that the estimated net effect of theological conservatism on the frequency of corporal punishment is stronger for blacks and Hispanics than for whites/Anglos, for fathers (because many Conservative Protestant households are organized in patriarchal fashion), and for parents with less education and income. In addition, we tested for variations in the effect of theological conservatism by the age and gender of the young child.

We also considered two additional possibilities: (1) It is reasonable to anticipate that, while many parents of various religious backgrounds value obedience in their children, the connection between such authority-minded values and the frequency of corporal punishment is stronger for theological conservatives. (2) Although many parents of all theological stripes may respond to repeated child misbehavior with corporal punishment, it is conceivable that certain types of persistent misbehavior (e.g., disobedience, cruelty to others)

may be especially likely to elicit physical punishment from theologically conservative parents. Ancillary analyses (not shown) yielded no clear support for any of these contingent hypotheses.

THE CORPORAL PUNISHMENT OF CHILDREN AGES 5-11

Table 3 presents logistic regression models estimating the net effects of Conservative Protestantism and covariates on the log odds of corporal punishment by the parents of children 5-11 years old. These models are organized in hierarchical fashion, similar to those presented in Table 2. Again, several patterns warrant attention. Model 1 indicates that membership in a Conservative Protestant denomination is associated with an increase of nearly 50% in the odds that responding parents spanked or slapped their grade school-aged child during the week prior to the NSFH interview, net of the confounding effects of respondent, household, and child characteristics. The inclusion of theological conservatism in model 2 reduces this association but does not attenuate it entirely. As in Table 2, theological conservatism remains a significant predictor of corporal punishment in models 3 and 4. In fact, these models reveal a slight suppressor pattern; the estimated net effect of theological conservatism actually increases somewhat once parental assessments of child behaviors are taken into account. In the full model (model 4), each increment in the theological conservatism index is associated with an increase of nearly 20% in the odds of spanking or slapping a grade school-aged child.

Thus, according to these estimates, the log odds of using corporal punishment in a given week are nearly 75% (.185 x [5-1] = .740) higher for a parent with the maximum score of 5 on this index — i.e., a strong theological conservative — than for a parent of similar background characteristics with the minimum score of 1 on the index — i.e., a strong theological liberal.

Parental affiliation with a Conservative Protestant denomination also bears a weak (and marginally significant) but positive association with corporal punishment throughout this panel of models. In the full model, the log odds of using corporal punishment are roughly 33% (exp [.284]) greater for a parent who reports affiliation with a Conservative Protestant group than for a parent with similar background characteristics who is not affiliated with such a denomination ($p < .08$). As in the analyses of the parents of focal toddlers and preschoolers, tests designed to identify various interactive or contingent relationships with the Conservative Protestant variables turned up no reliable evidence of such patterns.

ESTIMATED NET EFFECTS OF COVARIATES

Although the estimated effects of the covariates themselves are not the primary focus of our study, the NSFH data yield a number of useful insights into the antecedents of corporal punishment. Given the dearth of evidence on this topic, several empirical patterns involving covariates also merit brief discussion. Mothers of very young children and grade school-aged children use corporal punishment more frequently than fathers. Younger parents spank or slap their children more often than older parents, although the estimated net effect of

parent's age is attenuated in the models for grade school-aged children by controls for parents' assessments of child behavior. Parents with multiple toddlers and preschoolers also physically punish their children — including their older children — more frequently than other respondents. Taken together, these patterns are broadly consistent with the notion that parents who are inexperienced and stressed tend to spank or slap their children more often than others.

Given the substantial body of prior work associating socioeconomic differences in child rearing with *attitudes* toward corporal punishment mentioned at the outset of this study, it is interesting that household income and parental education are only relatively weak predictors of the *use* of corporal punishment, for younger and for older children.[10] While observers have long suggested that African Americans resort to corporal punishment more frequently than whites/Anglos (e.g., Alvy 1987), we find no substantial black-white

differences in the spanking of either toddlers or preadolescents once the effects of relevant sociodemographic and other background factors are held constant. Further, although we find no differences in the corporal punishment of grade school-aged children between Hispanics and whites/Anglos, Hispanic parents report spanking or slapping their toddlers and preschoolers less frequently than white/Anglo parents.[11]

Consistent with previous research (e.g., Wauchope & Straus 1990), we find that child characteristics and parental assessments of child behavior also have important implications for child discipline. In the NSFH, parents' use of physical force peaks around age 2, declines slightly at age 3, and then tails off considerably by age 4. Corporal punishment seems to plateau around ages 5-6, when the child is entering the school-age period, and then declines monotonically thereafter. There is also a substantial gender difference in the use of corporal punishment: Boys of all ages are spanked or slapped much more often than girls. Further, adopted grade school-aged focal children confront elevated risks of physical punishment; they are more than 50% more likely (exp [.413]) than other children to have been spanked or slapped by parental respondents during the week prior to the interview.

It is not surprising that respondents who evaluate their children as obedient use corporal punishment infrequently, while respondents who indicated that their young children engage in undesirable behaviors — i.e., that they are fussy or temperamental, or that they bully others — tend to employ physical force much more often. Given the cross-sectional nature of the NSFH data and the fact that child behaviors are measured from parental assessments rather than from observation, the causal process that underlies these empirical associations remains unclear. It is somewhat surprising that authority-minded parental values (i.e., valuation of children's obedience and conformity) are only modestly associated with the corporal punishment of children ages 1-4 and very weakly linked with the corporal punishment of older children, once the confounding effects of background factors are statistically controlled. This finding highlights the need to explore the factors that mediate the links between abstract, global parental values and concrete parental behaviors (Holden & Edwards 1989).

Discussion

After a long period of scholarly neglect, a small but growing literature has called attention to the relationships between Conservative Protestantism and attitudes toward the corporal punishment of children. Several studies have suggested that members of Conservative Protestant denominations are more likely to support the principle of corporal punishment than other persons (Erlanger 1974; Wiehe 1990). More recently, researchers have shown that such denominational variations may actually reflect the influence of specific conservative theological beliefs, particularly commitment to the doctrine of biblical inerrancy (Ellison & Sherkat 1993a; Grasmick, Bursik & Kimpel 1991).

We have extended this literature by linking conservative theological orientations with the actual *use* of physical punishment to discipline toddlers and preschoolers (ages 1-4) and grade school-aged children (ages 5-11). Analyzing data from a large national survey, we have presented new evidence

that parents who believe (1) that the Bible is the inerrant Word of God and (2) that it provides answers to all human affairs and problems use corporal punishment to discipline their children more frequently than parents with less conservative theological views. In addition, consistent with the thrust of some earlier research (e.g., Ellison & Sherkat 1993a), statistical controls for theological conservatism virtually eliminate the estimated effects of Conservative Protestant denominational affiliation. Further, the link between theological beliefs and the use of physical punishment persists even when the potentially confounding effects of numerous parental and household characteristics, child characteristics and behaviors, and global parental child-rearing values are taken into account.

While our findings underscore the importance of religious values — particularly those associated with Conservative Protestantism — for the study of child discipline, they also raise a number of important questions that warrant clarification in the future. First, the NSFH — like most large-scale surveys — does not contain detailed information on the *type* and *intensity* of corporal punishment. Anecdotal evidence suggests that terms like "spanking" and "slapping" may cover a variety of disciplinary practices, ranging from mild taps or swats on the buttocks to more determined beatings with belts and other objects, to the most severe forms of abuse. Obviously the levels of force and intensity implied by these differences, and the probable consequences for children, may vary considerably. Although some accounts suggest that Conservative Protestants are prone to use particularly violent forms of physical punishment (Capps 1992; Maurer 1982), much more information is needed on the diverse forms of corporal punishment administered by Conservative Protestants and other parents (Bartkowski 1995).

Second, given our finding that the comparatively frequent use of corporal punishment by conservative religious parents is *not* attributable to more negative *global* assessments of children's behavior, we need more information on how parents arrive at decisions on disciplinary responses to *specific* child misbehaviors under *particular* circumstances, and especially on how Conservative Protestant parents may differ from others in their decision-making processes. For instance, given the importance of themes of sin and punishment in Conservative Protestant theology and child-rearing philosophy, parents may be especially prone to interpret specific child misbehaviors as instances of "willful disobedience," to downplay alternative explanations for these misbehaviors (e.g., "childish irresponsibility"), and to deemphasize the role of other types of situational information (e.g., child illness, fatigue or emotional upset, parental stress). In this way, the distinctive theological views of Conservative Protestant parents may be introduced into the decision-making process, possibly leading parents to engage in a specific version of "the fundamental attribution error" — that is, to attribute misbehavior *dispositionally*, as a consequence of the child's character, rather than *situationally*, as a consequence of the circumstances surrounding the event (Grasmick & McGill 1994). A multimethod approach — involving not only standard survey instruments, but also personalized vignettes, in-depth interviews, and perhaps observational methods — will ultimately be required to investigate these and other possible religious variations in the parental decision making process.

Third, our findings almost certainly understate the frequency with which focal children in the NSFH are physically punished. This is the case because our analyses focus solely on the antecedents of spanking or slapping by one respondent parent. However, other adults may also employ physical punishment to discipline the child. This may be especially important for religious conservatives. Because rates of religious intermarriage are relatively low among Conservative Protestants (McCutcheon 1988), one suspects that many of the NSFH focal children — especially toddlers and preschoolers — who are spanked or slapped by a theologically conservative parent may also experience corporal punishment from the respondent's spouse or partner. It is reasonable to hypothesize that homogamous religious conservatives may use corporal punishment more often in part because pastors, friends, and family members are likely to provide sympathetic feedback about the value of "traditional" child-rearing practices. Although an empirical exploration of this issue lies beyond the scope of our study, it will be important for future researchers to examine the role of religious beliefs in shaping the congruence (or incongruence) of parental disciplinary preferences, as well as the ways in which parents' divergent views are harmonized in practice.

Finally, while sociologists have intermittently explored distinctive aspects of Conservative Protestant child-rearing practices (e.g., Nelsen & Kroliczak 1984; Nunn 1964), there is virtually no solid evidence on the short- or long-term effects of corporal punishment on the children of theologically conservative parents.[12] In light of our findings, such research is clearly needed. As we noted at the beginning of this article, numerous academic and popular experts have expressed alarm about the possible impact of physical punishment on various behavioral and developmental outcomes (see Straus 1994b). However, much of the research on the consequences of corporal punishment — especially mild to moderate forms — suffers from methodological weaknesses. With only a handful of exceptions (e.g., Weiss et al. 1992), work in this topic has relied heavily on cross-sectional (as opposed to longitudinal) data or on retrospective accounts of individuals' experiences of corporal punishment. Small community or convenience samples have also been the norm in this area. In addition, some researchers have also combined indicators of corporal punishment with indicators of tougher disciplinary practices — e.g., severe beatings, threats or assaults with knives and guns — to construct measures of "harsh punishment" or the like.

Although such omnibus measures are often correlated with negative child outcomes, they are of little help in specifying the effects of mild to moderate corporal punishment on children. Further, studies have routinely neglected to control for other aspects of child rearing (e.g., amount of quality time between parent and child, level of parental support and nurturance), which may be related to the use of physical punishment and may account for the empirical association between such punishment and negative child and adolescent outcomes (Simons, Johnson & Conger 1994). Moreover, only a few studies have investigated the potential mediating and moderating effects of various contextual factors (e.g., mode of administration, regularity and promptness, clarity of parental explanation) on the consequences of corporal punishment (Kurz 1991; Larzelere 1986, 1994; Larzelere et al. 1989). For these and other reasons, it may

be premature to draw firm conclusions about the effects of mild to moderate corporal punishment.

Nevertheless, if the concerns of many academic and popular child development specialists are on target, then we might expect to find that children from theologically conservative families — who as a group are more likely to experience frequent corporal punishment than others — exhibit heightened risk of various undesirable child and adolescent outcomes. Yet leading Conservative Protestant commentators adamantly contend that prudent physical discipline is essential for *preventing* such outcomes and for raising healthy, happy, Christian children (Christenson 1970; Daugherty 1991; Dobson 1970, 1976; LaHaye 1977; Swindoll 1991). And while the empirical evidence is not unequivocal, a number of studies over the years have reported that religiosity and religious participation among youths — especially those from conservative backgrounds — are associated with lower risk of substance use and abuse, other forms of delinquent behavior, teen pregnancy, and even academic failure (e.g., Beck, Cole & Hammond 1991; Burkett 1993; Stark 1984).

Why might corporal punishment have fewer harmful (perhaps even some beneficial) consequences for Conservative Protestants than for other youths? We suggest two possible reasons. First, the effects of even frequent spanking or slapping may be less damaging in cultural contexts in which the practice of corporal punishment is widely accepted as legitimate. It is conceivable that the discourse within Conservative Protestant families, churches, and communities — where corporal punishment has been the norm for many generations (Greven 1977) — may mitigate the negative emotions (among children and parents) that sometimes accompany physical punishments in other contexts. Second, Conservative Protestants may implement this punishment differently from other parents. For instance, religious child-rearing manuals often devote considerable attention to the details of administering corporal punishment, instructing parents on when to spank, what type of "rod" to use, how and where to hit the child safely, and so forth (e.g., Dobson 1976 and Lessin 1979; see Bartkowski 1995; Ellison & Bartkowski 1996; Greven 1990). As we noted earlier, while a few religious commentators advocate the broad use of relatively harsh corporal punishment (Fabrizio 1969; Fugate 1980), the most popular of these authors (Christenson 1970; Dobson 1970, 1976; Swindoll 1991) recommend the use of moderate physical force only in clear instances of "willful disobedience." Further, they specifically counsel against spanking when the parent is angry or when the behavioral infraction involves childish irresponsibility or some other well-intentioned mistake. These authors are careful to distinguish moderate corporal punishment from physical abuse, and to warn parents about the potential for escalation (Dobson 1976:73-76; Swindoll 1991:82-85). Moreover, several leading Conservative Protestant commentators also advise parents to initiate a period of intimacy and affection with the child after the punishment (Christenson 1970; Dobson 1976).

In short, such mild to moderate spanking would differ substantially from the frustrated, hostile use of physical force decried by academic and popular parenting specialists alike. Of course, to date there is little empirical information on the precise methods of implementation actually used by theologically conservative parents, or the extent to which their practices in this area parallel

those recommended by Dobson and others. Similarly, it is unclear whether the effects of such methods would be more benign than the negative consequences associated with harsher practices. Given that religious conservatives almost certainly constitute the largest and best-organized constituency advocating the use of corporal punishment, the resolution of these issues should be an important priority of researchers in the future.

Notes

1. Here we use the term *Conservative Protestant* as an umbrella term to refer to fundamentalists and other evangelicals. Although the fundamentalist label is sometimes used in precisely such an inclusive fashion, this label is hotly contested. Many evangelicals reject the fundamentalist label because of its pejorative connotation in the media and in broader society and because of various religious and political differences with fundamentalists.

2. We use these insider documents to clarify the worldview of Conservative Protestants with regard to issues of child discipline. We do not assume that these child-rearing manuals influence the practices of parents, but only that these authors generally reflect and articulate the views and sensibilities of religious conservatives. Because our goal is to identify common themes in this popular literature, we necessarily downplay the heterogeneity on some issues within the conservative camp (Bartkowski 1995; Ellison & Bartkowski 1996). In addition, while our work focuses on contemporary religious conservatives, Greven (1977) has called attention to the considerable continuity between their views on child rearing and those of many early American evangelicals.

3. While most prominent Conservative Protestant child-rearing writers endorse such beliefs in original sin, their beliefs are not unanimous. For instance, Campbell (1989, 1992) argues that many writers in this genre exaggerate the salience of themes of sin and punishment at the expense of a more fundamental message of divine love and mercy.

4. Some researchers have suggested that indicators tapping variations in religiosity or religious participation may be more closely related to family attitudes and practices than denominational ties or theological orientations (e.g., Alwin 1986). Therefore, we also constructed an eight-point ordinal measure of the frequency of church attendance similar to that included in the General Social Surveys. This variable was unrelated to the frequency of corporal punishment.

5. The NSFH interview schedule also contains a third item tapping Conservative Protestant sensibilities. This item asks respondents to indicate their level of (dis)agreement with the following statement: "I regard myself as a religious fundamentalist." This item seems less closely related to the theoretical arguments outlined earlier than the items on Bible beliefs. Further, because the term *fundamentalist* has no clear translation in Spanish, the inclusion of this item would require dropping a small number of Hispanics who completed the interview in Spanish. For these reasons, we omit the "fundamentalist" item from our analyses.

6. These indicators of child behaviors are moderately intercorrelated ($.20 < r < .35$). However, they do not comprise a satisfactory index ($\alpha < .55$) in any combination, and the increment to R^2 is greater when they are added individually as predictors of the frequency of corporal punishment.

7. The numbers of Asian and Pacific Islanders, Native Americans/American Indians, and various other categories were too small to analyze, and these groups were dropped from the models that follow. In addition, the numbers of Puerto Ricans (even with oversampling) and Cuban Americans were still too small for separate analyses of these diverse segments of the Hispanic (Latino) population. Although the NSFH also oversampled cohabitors, there are not enough cohabiting respondents who are parents of focal children to permit meaningful analysis.

8. Given the hierarchical structure of these OLS regression models, one possible interpretation of this finding is that authority-minded parents are prone to evaluate their children's behavior negatively. Because the preoccupation with issues of authority and (dis)obedience may influence the encoding and interpretation of child conduct, and hence the overall assessment of child behaviors during the period prior to the interview, one might expect that the estimated

net effect of parental child-rearing values would be slight once the potentially confounding effects of these assessments were taken into account. However, ancillary models (not shown) cast doubt on this interpretation; when we estimated models that *included* parental values and *excluded* parents' reports of child conduct, the results did not change.

9. We acknowledge some potential for response bias. Theologically liberal respondents may tend to understate their "true" or accurate levels of corporal punishment for fear of inviting disapproval from the interviewer or from their fellows. On the other hand, religious conservatives may be inclined to respond accurately, or even to exaggerate their use of such disciplinary techniques, because their use is approved and encouraged within many Conservative Protestant communities. Of course, all respondents, but especially conservative religious parents, who spank or slap their children may also be inclined to underestimate the frequency of these practices, due to the specter of intervention by local or state social service agencies concerned with child protection. Therefore, we doubt that response bias adequately accounts for the empirical patterns discussed in the text.

10. In additional analyses (Ellison, Bartkowski & Segal 1996), we estimated the effects of Conservative Protestantism and covariates on an ordinal measure of the frequency of corporal punishment (with response categories "never," "seldom," "sometimes," or "very often") asked of all NSFH primary respondents who were parents of children under 12 living in the home. While most findings paralleled those reported in the text, it is interesting that both household income and (particularly) parental education emerged as significant inverse predictors of the frequency of corporal punishment in those analyses. The meaning of this discrepancy is not entirely clear, but one possibility is especially intriguing: Some better-educated and more affluent parent respondents may have provided (what for them may be) socially desirable responses, underestimating their frequency of corporal punishment when presented with vague, ordinal response categories. Such "hedging" may have been more difficult for parental respondents who were asked for a more precise count covering the week prior to the NSFH interview.

11. Because southern and rural residence are related to attitudes toward corporal punishment (e.g., Flynn 1994), we included these variables in preliminary models. When both residential variables were consistently unrelated to the frequency of corporal punishment, they were dropped from subsequent analyses.

12. Nelsen and Kroliczak (1984) and Nunn (1964) present evidence that parents' use of the threat that "God will punish" — perhaps particularly characteristic of Conservative Protestant households — may promote self-blame and obedience in children. However, they report that the impact of these parental "coalitions with God" on the development of internal controls seems to depend on images of God and perhaps other factors as well. Additional research is needed to determine whether physical punishment helps to promote internal controls among Conservative Protestant youths.

Gender Ideology and Perceptions of the Fairness of the Division of Household Labor: Effects on Marital Quality*

THEODORE N. GREENSTEIN, *North Carolina State University*

Abstract

Under what circumstances will married women perceive inequalities in the division of household labor as unfair? This research develops and tests a model based on relative deprivation theory that suggests that gender ideology functions as a moderator variable in a process through which inequalities in the division of household labor come to be seen as inequities. Using data from the National Survey of Families and Households, three empirical tests of the model provide evidence that inequalities in the division of household labor are more strongly related to perceptions of inequity for egalitarian than for traditional wives, and that perceptions of inequity are more strongly related to perceived quality of the marital relationship for egalitarian than for traditional wives. The findings suggest that researchers studying the division of household labor need to shift their focus away from analyses of objective inequalities and toward the study of perceived inequity.

Gender-based inequality in the division of household labor has become a key issue for scholars of marriage and the family. Research has found that although married women perform the majority of household labor, relatively few wives feel that this arrangement is unfair. The purpose of this study is to present and test a model that explains how and why *inequalities* in the household division of labor come to be perceived by some wives as *inequities,* and how those perceptions affect marital quality.

** The National Survey of Families and Households was funded by a grant (#HD21009) from the Center for Population Research of the National Institute of Child Health and Human Development. The survey was designed and carried out at the Center for Demography and Ecology at the University of Wisconsin-Madison under the direction of Larry Bumpass and James Sweet. The fieldwork was done by the Institute for Survey Research at Temple University. Maxine Atkinson, April Brayfield, Donald Tomaskovic-Devey, and two anonymous* Social Forces *reviewers made valuable comments on an earlier draft of this article. The analyses and interpretations herein are those of the author. Please direct correspondence about this manuscript to Theodore N. Greenstein, Department of Sociology and Anthropology, North Carolina State University, Raleigh, NC 27695-8107 (Internet ted_greenstein@ncsu.edu).*

 Social Forces, March 1996, 74(3):1029-1042

Two key findings in this literature have been that (1) wives perform far more household labor than do their husbands, and that (2) the kinds of household tasks performed by wives and husbands differ. Blair and Lichter's (1991) recent analysis of the National Survey of Families and Households produced results typical of most studies. They found that women perform an average of 33 hours of household tasks (exclusive of child care) per week, compared to men's average of 14 hours. Many researchers (e.g., Blair & Lichter 1991; Brayfield 1992; Mederer 1993) have also noted that household labor remains highly segregated by sex; those tasks that have traditionally been thought of as "women's work" (e.g., cooking, laundry, housecleaning) are primarily performed by women, while "male" tasks such as yard work and auto maintenance are done primarily by men.

The central concern of this article is not with the amount or *content* of household tasks nor is it with the sources or amount of *inequality* in the division of those tasks. Rather, the focus is on the consequences and perceptions of those inequalities. The model starts from the empirical generalization that husbands tend not to share equally in the division of household labor, even when their wives are employed full-time. The consensus of dozens of studies of this issue is that the level of a husband's contribution to family work is not strongly related to his wife's employment status (e.g., Berk 1985; Huber & Spitze 1983; Pleck 1985; Shelton 1990). A finding of Demo and Acock (1993) on this issue was that while husbands of employed wives contribute on average 4.3 more hours per week on chores than do husbands of unemployed wives, the division of household labor remains strikingly unequal: employed wives' proportion of total hours spent on household chores is still about 72% and about 81% for unemployed wives. The division of household labor is relatively traditional — that is, the wife performs a far greater proportion of household tasks than does her husband — in households where the wife earns more than her husband (Atkinson & Boles 1984) and even in households where the husband is not employed (Brayfield 1992). When married women work outside the home, their combination of market and nonmarket work is likely to force them into working what Hochschild calls the second shift (Hochschild with Machung 1989).

Unquestionably, there *are* gender-based inequalities in the division of household labor. However, even though most wives do the bulk of household tasks, relatively few wives feel that this division of labor is unfair (see, e.g., Benin & Agostinelli 1988; Berk 1985; Pleck 1985; Yogev 1981). The key issue here deals with *perceptions* of justice: under what circumstances will *inequalities* in the division of household labor come to be perceived as *inequities*? To answer this question, we need to consider the theoretical literature on justice.

Relative deprivation theory (Crosby 1976) makes several crucial assumptions about the nature of justice. First, it is the *subjective* evaluation of outcomes that determines whether one feels unjustly treated. Second, individuals must *value* an outcome in order for justice phenomena to become relevant. Third, perceptions of injustice or inequity are the results of *comparison processes*. It is axiomatic that no justice phenomenon can arise in the absence of a stable frame of reference. Finally, the theory suggests that there is *preference for equity* in relationships, and that when individuals perceive that they have been unjustly

treated they will feel distressed and will be motivated to take action to restore equity.

From a relative deprivation perspective, an outcome is equitable when it is similar to that of some comparative referent (another person, a group, past experience, one's expectations). When an outcome falls short of what is expected, the individual in question will feel deprived in a relative sense (even though in absolute terms the individual may not be deprived at all). The relative deprivation approach has been quite fruitful in the study of justice in the family (e.g., see Major 1993; Sanchez 1994; Thompson 1991; Thompson & Walker 1989).

Major (1987) argues that three key elements contribute to perceptions of fairness: outcome values, comparison referents, and justifications. Gender ideology provides a mechanism through which these elements may be understood in the context of the perceived fairness of the division of household labor. Traditional women differ from nontraditional or egalitarian women in what they want out of their marital relationship (outcome values), the standards they use to judge their reward structure (comparison referents), and their perception of the legitimacy of reward allocation schemes (justifications).

Crucial to my explanation is the assumption that married women will have different reactions to an unequal division of household labor that are contingent on their gender ideology. I argue that the wife's gender ideology functions as a kind of lens through which inequalities in the division of household labor are viewed. According to the nature of that lens, such inequalities may be perceived as unfair or fair, inequitable or equitable. In effect, gender ideology serves to provide married women with a comparative referent.

Although the effects of gender ideology and inequalities in the household division of labor on marital quality have been studied (for example, Blair & Johnson 1992; Piña & Bengtson 1993), these effects have typically been modeled in an additive rather than interactive fashion. That is, most researchers that have included measures of ideology in their analyses of the household division of labor have assumed that gender ideology functions as a *mediator* variable (but see Bielby & Bielby 1992 and John, Shelton & Luschen 1995 for examples of research that conceptualize ideology as a moderator variable). The model proposed here explicitly assumes that inequalities in the division of household labor affect factors such as marital quality and perceptions of fairness in different ways for traditional than for nontraditional or egalitarian wives. In other words, I conceptualize gender ideology as a *moderator* (rather than a mediator) variable.

Why should married women of different gender ideology differ in their reactions to inequalities in the household division of labor? In the context of Major's (1987) model, I can suggest three possibilities. First, wives probably differ in the relative value they place on the various outcomes and characteristics of their marriages. Traditional wives might value stability and harmony in their relationships, while egalitarian wives might be more concerned with independence and autonomy.

Second, wives probably differ in their choice of comparison referents. A wife might not perceive the inequality in the household division of labor as inequitable because she might feel that her rewards are consistent with either

(1) What she expects to receive based on her past experiences, or
(2) What she expects to receive based on what she perceives that similar wives typically receive, or
(3) The referent group to which she compares herself

Gender ideology probably affects all three of these possible comparison referents. For example, traditional women might base their expectations about the household division of labor on their past experiences or those of their siblings or mothers; they might base them on what they perceive other wives receive; or they might base their expectations on the reference group of women who are ideologically and economically similar to themselves. Egalitarian women, on the other hand, will use very different comparison referents: other egalitarian wives, or perhaps expectations about how egalitarian marriages are supposed to be structured.

Third, wives may differ in their reactions to inequalities in the division of household labor according to whether they see the outcome as the result of a legitimate or justifiable process. If a wife truly believes that married women — even those employed full-time — are "supposed" to do the bulk of the housework with little assistance from their husbands, then she will probably see this inequality as resulting from a legitimate process, and not view it as unjust or inequitable. Some research (e.g., Crosby 1982; Kanter 1977) even implies that wives who are especially economically dependent on their husbands and cannot easily change their situation may come to believe that they "deserve" this inequality rather than concluding that they are being treated inequitably.

When a married woman perceives the division of household labor to be unjust, her reactions may take one of several forms (Major 1987; Mark & Folger 1984). She may direct her reactions to the perceived inequity at the *system* of marriage itself. She might attempt to change the structure of her marriage by encouraging her husband to contribute more household labor; failing that, she might become resentful and unhappy with her marriage, increasing the level of conflict and likelihood of separation and divorce. Alternatively, she might attempt to cognitively restructure the situation in an attempt to resolve the injustice. For example, she might devalue the *outcome* in question ("I don't really care if I have to do all the housework") or her *contributions* ("What I do isn't that important, anyway") or *revalue* the contributions of her partner ("What he does is more important than what I do" or "His job pays more").

Hypotheses

What predictions concerning the perceptions of married women can we base on the relative deprivation model? First, it is reasonable to expect that wives' reactions to the unequal division of household labor will be contingent upon their gender ideology. Traditional women — those who accept the "doctrine of separate spheres" where the ideal marriage consists of an economically successful husband and a dependent, nurturing wife — will view the additional workload created by the unequal division of household labor as consistent with their ideology and therefore not necessarily unjust. Nontraditional or egalitarian women, on the other hand, will find this inequality in the division of household

labor onerous and inequitable. Consequently, I expect to find that *inequalities* in the division of household labor are more likely to be perceived as *inequities* by nontraditional wives than by traditional wives. That is, the extent of the inequality in the division of household labor will be a better predictor of feelings of injustice or unfairness for nontraditional wives than for traditional wives. Gender ideology and the actual division of household labor should interact in their effects on perceived fairness of the division of household labor.

Second, I expect to find that gender ideology also moderates the effects of wives' perception of injustice in the division of household labor on the perceived quality of their marriages. While perceived fairness will probably affect the perceived quality of marriage for all married women, it should have a stronger effect for egalitarian or nontraditional wives than it does for traditional wives. Gender ideology and perceived fairness of the division of household labor should interact in their effects on perceived marital quality.

Data and Measurement

The data for these analyses come from the first wave of the National Survey of Families and Households (NSFH; Sweet, Bumpass & Call 1988). The NSFH is a national probability sample of 13,017 adult respondents interviewed in 1987 or 1988. In married couple and cohabiting households, a questionnaire was also administered to the respondent's spouse or partner. The analyses here focus on the 4,960 married couples (out of an unweighted total of 5,640) where both wife and husband responded to the survey and provided codable responses to all the items under study here. All analyses used the NSFH couple weights to adjust for oversampling, differential probabilities of selection, and differential response rates.

DEPENDENT VARIABLES

Perception of Fairness of the Division of Household Labor

NSFH respondents were asked "How do you feel about the fairness in your relationship in each of the following areas?": household chores, working for pay, spending money, and child care. The responses to the household chores item were used as an indicator of perceived fairness of the division of household labor. Response choices and their codings were "very unfair to me" (coded −1), "somewhat unfair to me" (−0.5), "fair to both" (0), "somewhat unfair to her/him" (+0.5), and "very unfair to her/him" (+1).

Perceived Marital Stability

NSFH respondents were asked "It is always difficult to predict what will happen in a marriage, but realistically, what do you think the chances are that you and your husband/wife will eventually separate or divorce?" Response choices were "very low" (coded as 5), "low" (4), "about even" (3), "high" (2), and "very high" (1).

Marital Happiness

NSFH respondents were asked, "Taking all things together, how would you describe your marriage?" Response choices ranged from "very unhappy" (1) to "very happy" (7).

INDEPENDENT VARIABLES

Indicators of Household Labor

Each spouse was asked to indicate "the approximate number of hours per week that you, your spouse/partner, or others in the household normally spend doing" preparing meals, washing dishes, cleaning house, outdoor tasks, shopping, washing and ironing, paying bills, auto maintenance, and driving other household members to work and school. Time spent in these tasks was totaled into measures of total hours spent by wives, husbands, children, and others doing household labor. An overall measure of the proportion of total household labor performed by the wife was then created.

Inspection of the NSFH household labor data shows that many respondents reported spending more than 168 hours per week on a combination of domestic and market work. Such responses may reflect invalidity in the self-reports of hours spent in household labor or the fact that many household tasks are performed concurrently. To adjust for this problem, any respondent who reported spending more than 100 hours per week in any one domestic work activity was coded as having spent 100 hours in that activity.

Wife's Traditionalism

NSFH respondents were asked a series of questions that were used to construct a summated scale of gender ideology. On a 1-7 scale where 1 = "strongly approve" and 7 = "strongly disapprove," respondents were asked how much they approved of "mothers who work full-time when their youngest child is under age five" and "mothers who work part-time when their youngest child is under age five." On a 1-5 scale, where 1 = "strongly agree" and 5 = "strongly disagree," respondents were also asked how much they agreed with the following four items: "It is much better for everyone if the man earns the main living and the woman takes care of the home and family"; "Preschool children are likely to suffer if their mother is employed"; "Parents should encourage just as much independence from their daughters as in their sons"; and "If a husband and wife both work full-time, they should share housework tasks equally." The six items were standardized and summed, yielding a Cronbach's alpha of .68. The summated scale was standardized to a mean of 100 and standard deviation of 15. Item scoring was reversed to produce a scale in which higher scores indicate more traditional ideologies.

CONTROL VARIABLES

There are a number of background characteristics of the wives, their husbands, and their marriages that I included in the model: race, wife's education in years, wife's and husband's market hours worked per week, census region of residence, residence in an SMSA, marital duration in years, and number of

children in the household. Each of these variables is potentially related to the independent and dependent variables described above.

Analysis and Results

DESCRIPTIVE STATISTICS

Table 1 presents weighted means and standard deviations for the entire sample of women and (for descriptive purposes only) three gender ideology subgroups created by dividing the total sample into thirds based on their gender ideology scale score. Overall, the women in the sample are fairly representative of the population of U.S. women who were married during the study period (1987-88). They had been married an average of 22.9 years. About 7 percent are African American, and about 6 percent are Hispanic. The women tended to have some postsecondary education, with a mean of 12.6 years of formal education. Most of the wives were employed at the time of the interview, averaging about 18.5 hours per week in the paid labor force. The households had an average of 1.03 children under the age of 18 years.

The descriptive statistics on the division of household labor are consistent with those of previous studies. Wives averaged about 37 hours per week in household tasks (exclusive of child care), while husbands averaged about 16 hours. Wives performed about 64% of all household labor (including household labor performed by children and others in the household).

Not surprisingly, the women in the gender ideology subgroups differ substantially (the differences in group means are statistically significant beyond the .05 level for all variables except metropolitan residence and living in the Northeast or North Central regions). For example, egalitarian women were more likely to feel that the division of household labor was unfair, perceived a greater chance of their marriages ending in divorce, and were less likely to respond that they were "Very happy" with their marriages. Traditional women in the sample tend to have been married longer, to have less formal education, to spend more time doing domestic labor, and to work fewer hours outside the home. Consistent with earlier studies, traditional women performed a greater proportion (67%) of the domestic labor than egalitarian women (59.9%).

ANALYSES OF PERCEPTIONS OF FAIRNESS OF THE DIVISION OF HOUSEHOLD LABOR

The second column of Table 2 presents the results of an OLS regression analysis for all wives modeling the effects of 13 predictor variables on perceived fairness of the division of household labor. Overall, this model accounts for about 4.4% of the variation in the dependent variable. Six of the predictors have significant effects on perceptions of fairness of the division of household labor. Wives with longer marital durations are more likely to perceive the division of household labor as fair, as are Hispanic wives. Perception of the division of household labor as fair decreases as the wife's total hours spent performing household tasks and hours in market labor increase, but increases as the husband's contributions to household labor increases. Most important, there is a statistically significant interaction between the wife's share of the domestic labor and

TABLE 1: Descriptive Statistics for Variables in Analyses[a]

	All Wives	Wife's Gender Ideology: Egalitarian	Transitional	Traditional
Unweighted sample size	4,960	1,656	1,647	1,657

Region of residence				
Northeast (percent)	19.7	21.1	19.3	18.9
North central (percent)	26.0	27.4	26.8	24.0
South (percent)	35.3	34.2	34.0	37.6
Percent in SMSA	73.7	75.9	73.0	72.6
Number of children in household	1.03 (1.25)	1.10 (1.14)	0.96 (1.20)	1.04 (1.37)
Hours spent in:				
Domestic labor by wife	36.8 (23.4)	32.4 (20.9)	37.4 (23.5)	40.2 (24.6)
Domestic labor by husband	16.1 (15.4)	17.6 (15.4)	16.1 (16.0)	14.8 (14.7)
Market labor by wife	18.5 (19.8)	26.1 (19.9)	18.2 (19.6)	12.0 (17.5)
Market labor by husband	33.4 (22.2)	38.0 (19.9)	32.2 (22.4)	30.5 (23.3)
Wife's percent of domestic labor (percent)	63.9	59.9	64.4	67.0
Wife's traditionalism	100.3 (15.5)	82.2 (9.1)	100.5 (3.5)	116.0 (8.1)

[a] Table entries are means and, in parentheses, standard deviations (for continuous variables) and percentages for categorical variables.

gender ideology: as gender ideology becomes more traditional, the effect of inequalities in the household division of labor on perceived fairness decreases.

I should point out that, although these findings are consistent with most of the empirical studies of the division of household labor, there are marked differences with Blair and Johnson's (1992) findings from the same NSFH data set. They found no significant effects of wives' market labor on perceptions of unfairness, and noted that "ideological variables appear to explain very little of the variation in wives' perceptions of fairness" (579). There are sizable differences between the samples under analysis in the present study and that of Blair and Johnson; my sample size is 4,960 couples, whereas Blair and Johnson's is 778. Part of this difference is attributable to Blair and Johnson's exclusion of black and Hispanic wives from their analyses, and part is due to the limitation of their sample to primary respondents only.

ANALYSES OF MARITAL HAPPINESS

Column 3 in Table 2 presents the results of an OLS regression analysis for all wives modeling the effects of 13 predictor variables on the measure of the wife's self-reported marital happiness. Overall, the model accounts for about 7.5% of the variation in the dependent variable. In general, the results from this model are consistent with those of similar studies (e.g., Blair 1993; Perry-Jenkins & Folk 1994). African American wives tend to have lower levels of marital happiness; wives in the Northeast and South tend to have higher marital happiness scores. Wives' marital happiness increases as market labor hours increases. The interaction between wife's gender ideology and perceptions of fairness, although not reaching conventional levels of statistical significance (the effect is statistically significant using a one-tailed test at the .07 level), is in the predicted direction: perception of fairness of the division of household labor affects marital happiness more strongly for egalitarian wives than for traditional wives.

ANALYSES OF PERCEPTIONS OF MARITAL STABILITY

Column 4 of Table 2 presents the results of an OLS regression analysis for all wives modeling the effects of 13 predictor variables on the measure of the wife's perceptions of marital stability. Overall, the model accounts for about 9.3% of the variation in the dependent variable. Women with longer marital durations, those with more education, those living in the Northeast and North Central regions, and those employed more hours tend to perceive that their marriages are more stable. On the other hand, being African American and having more children negatively affect perceptions of marital stability. The interaction between perceived fairness of the division of household labor and gender ideology is statistically significant and in the predicted direction: perceived fairness affects perceived marital stability more strongly for egalitarian wives than it does for traditional wives.

TABLE 2: OLS Regressions Predicting Perceived Fairness of Division of Household Labor and Measures of Marital Quality[a]

MULTIVARIATE TEST OF THE INTERACTION HYPOTHESIS

To assess the overall hypothesis that gender ideology and perceptions of fairness of the division of household labor interact in their effects on perceived general marital quality, I performed a multivariate test across the two analyses of marital quality measures reported above. Wilks's lambda for these data is .998 with a corresponding F statistic of 4.60 at 2 and 4,941 df, $p = .011$. Thus, we can confidently reject the null hypothesis that there is no interaction between gender ideology and perceptions of fairness of the division of household labor in their effects on marital quality. Perceptions of fairness of the division of household labor *do* appear to affect perceptions of marital quality more strongly for egalitarian wives than for traditional wives.

Discussion

The central issue under study in this research was, under what circumstances will wives perceive inequalities in the household division of labor as inequitable or unjust? Even though most wives do most of the household labor, relatively few wives feel that their household division of labor is unfair. Apparently, *inequalities* in the division of household labor are not always perceived by married women to be *inequities*. Applying relative deprivation theory to the analysis of this situation, I assumed that gender ideology provides a comparative referent that married women use to evaluate the fairness or justice of their household division of labor.

Given that husbands tend not to share equally in the division of household labor, all women — regardless of gender ideology — have to work more total hours (that is, both market and nonmarket labor) as their participation in the market labor force increases. For women holding traditional gender attitudes, it is plausible that this "second shift," while undoubtedly stressful, would not necessarily contribute to perceptions of marital quality because such unequal allocations of responsibility for household labor are consistent with the expectations of a married woman holding a traditional gender ideology. Consequently, traditionally oriented women would not necessarily perceive these inequalities as inequitable. Nontraditional women, on the other hand, are likely to perceive such inequalities as inequitable; their expectations of an egalitarian relationship with their spouse are violated by being forced to work a "second shift." Their reaction to this inequity would typically manifest itself as increases in conflict with their husbands, a decline in marital satisfaction and happiness, and a greater likelihood that their marriages would experience a separation or divorce.

The first hypothesis predicted that wives who subscribe to nontraditional or egalitarian gender ideologies are most likely to view inequalities in the division of household labor as inequitable. The analyses reported in Table 2 confirm this hypothesis; inequalities in the division of household tasks are related to the likelihood that an egalitarian wife sees the division of household labor as unfair; for traditional wives, the division of household labor is not related to perceptions of injustice.

My second hypothesis suggested that perceptions of inequity in the household division of labor will affect marital quality more strongly for egalitarian or nontraditional wives than it does for traditional wives. Two empirical tests — effects on wives' perceptions of marital stability and wives' reports of marital happiness — confirmed this hypothesis.

Some authors have suggested that ideological factors are not important determinants of wives' perceptions of fairness of the division of household labor. Blair & Johnson (1992), for example, concluded that "ideological variables appear to explain very little of the variation in wives' perceptions of fairness" (579), although they found a statistically significant effect of family labor ideology and perceptions of fairness of the division of household labor for employed wives, particularly for younger wives. The present analyses suggest that the role of gender ideology in this process is that of a moderator variable. While ideology does have effects on perceptions of inequity in the division of household labor — egalitarian wives are more likely to perceive the division of household labor as unfair than are traditional wives — its most theoretically compelling effect is that it moderates the perceptions of inequities as well as perceptions of marital quality.

One important direction for future research is to study the role of husbands' gender ideologies on their perceptions of fairness and marital quality. The present research used relative deprivation theory to understand the linkage between wives' ideologies and perceptions. However, it seems unlikely that relative deprivation theory will prove to be a fruitful approach to understanding husbands' perceptions. The motivating factor underlying justice phenomena is the perception that there is a gap between what one expects to receive and what one anticipates, leading to a belief that one is being inequitably treated. For most husbands, this gap (at least relative to domestic work) simply does not exist; the husbands in this study performed on average only about 30% of the domestic work. Thus it seems unlikely that husbands' perceptions and behaviors can be meaningfully modeled within a relative deprivation framework.

In conclusion, this research finds that relative deprivation theory can be useful in understanding why inequalities in the household division of labor are not necessarily perceived by married women as unfair or inequitable and how this justice phenomenon is related to marital quality. Gender ideology serves as a comparative referent to which married women compare their own division of labor. When their own outcomes are consistent with that comparative referent, the situation is likely to be judged as fair. When these outcomes are inconsistent with that referent, the situation is likely to be perceived as unfair. Consistent with this theory, traditionally oriented wives are less likely to judge their household division of labor as unfair than are nontraditional or egalitarian wives. Further, perceptions of fairness or justice in the household division of labor are more strongly related to marital quality for egalitarian than for traditional wives.

These findings are consistent with recent studies (e.g., Blair 1993; Perry-Jenkins & Folk 1994) that find that wives' *perceptions* of the fairness of the division of household labor are better predictors of marital conflict than the *actual* extent of inequality. Relative deprivation theory suggests that the unequal division of household labor will have consequences for marital quality only

when that inequality is perceived to be unjust. One important implication of these findings is to shift our focus from the *objective* level of inequality in the division of household labor to the *subjective* or cognitive processes by which these inequalities come to be perceived as inequities.

Ideology, Power, and Equity: Testing Competing Explanations for the Perception of Fairness in Household Labor*

ALFRED DEMARIS, *Bowling Green State University*
MONICA A. LONGMORE, *Bowling Green State University*

Abstract

Previous explanations of couples' tendency to see their household division of labor as fair primarily support the influence of three factors, net of partners' actual contributions to "female-typed" housework. The three are partners' adherence to a traditional gender role ideology, wives' limited alternatives to the marriage, and equity across key domains of the relationship. Using responses from 2,109 male and 2,096 female marital partners from the National Survey of Families and Households 1987-88, we examine the relative efficacy of these factors in accounting for variation in the perception that housework is unfair to the wife. We find most support for the effect of ideology and considerations of equity and relatively little for wives' alternatives, at least when the latter are measured by wives' general human capital. The findings suggest ways in which partners' negotiations are constrained by gender role beliefs.

Objectively, the division of household labor is clearly inequitable to women. Regardless of their employment status, wives perform, on average, more than twice as much housework as their husbands (Hartmann 1981; Presser 1994; Shelton 1990; Thompson & Walker 1989). Nevertheless, only about a third of husbands or wives perceive this situation to be unfair to wives (Lennon & Rosenfield 1994). The reasons for this apparent paradox have been investigated in a spate of recent studies (Blair & Johnson 1992; Glass & Fujimoto 1994; Lennon & Rosenfield 1994; Perry-Jenkins & Folk 1994; Piña & Bengtson 1993; Sanchez 1994; Ward 1993). Three explanations predominate for the prevalence of a sense of justice among spouses. The first is ideology: To the extent that societal norms define most household tasks as "feminine" activities, individuals

* ***This is a revised version of a paper presented at the annual meeting of the American Sociological Association, 6 August 1994, Los Angeles, CA. will accept a division of labor in which the wife performs most of the chores. The second is power: To the extent that a woman has few alternatives to the relationship, particularly with respect to financial support, she will have little leverage with which to effect change. Her expectations for justice in housework will be correspondingly lower, thereby enhancing the apparent fairness of existing arrangements. The third is equity: To the extent that partners perceive husbands as compensating for a low input in household labor with greater inputs in other important domains of the relationship, such as paid work or child care, individuals will feel that women's greater contributions to housework are justified.

With data on more than 2,000 couples from a recent large probability sample of U.S. households, we test the relative efficacy of these three explanations in accounting for couples' perceptions of housework fairness, net of partner differences in the actual performance of housework. Both married and unmarried cohabiting couples are employed in the analyses; the terms *husband* and *wife* will be used throughout to refer generically to unmarried as well as married intimate partners. Unlike several other analyses, we examine both husbands' and wives' perceptions of housework justice, rather than just those of the wife. Also, in contrast to most previous studies on this topic, we examine the impact of partners' relative contributions to child care on perceptions of fairness in housework. Child care represents one of several domains of the relationship other than housework per se that, under an equity model, may affect perceptions of fairness. We begin by reviewing theoretical and empirical literature pertaining to the perception of housework fairness.

Theoretical Background

HOUSEWORK AND GENDER

Household work is a gendered activity, particularly for those in marital or quasi-marital relationships (South & Spitze 1994). Not only is the bulk of housework performed by women, but these tasks are also allocated disproportionately according to gender. Women are chiefly responsible for tasks such as cooking, washing dishes, doing laundry, and cleaning house, and men tend to be responsible for tasks such as home repair, automobile maintenance, and yard work. Other jobs such as grocery shopping or paying bills appear to be more evenly divided between the sexes (Bergen 1990; Nyquist et al. 1985; Ross 1987). Following Schooler et al. (1984), we refer to "female typed" tasks as "routine" and all others as "sporadic," to highlight the differences in time commitment that characterize these tasks: Routine work must ordinarily be done daily, whereas other tasks allow greater flexibility in scheduling. Women additionally have the primary responsibility for the planning and supervision of such tasks. This "executive" responsibility has led Schooler and his associates to observe that for women, unlike men, housework "is an imperative with psychological effects similar to those of the structural imperatives of paid employment" (122).

A "just" division of labor in the home would therefore be one in which men shared equally both in the performance of *all* household chores and in the

responsibility for seeing to it that housework is done (Perry-Jenkins & Folk 1994). Here justice is defined in the narrow sense as the equality of partners' contributions to each type of work required to sustain the household. (Below we argue that equity — a form of justice that subsumes equality as a special case — may be as influential, if not more so, in partners' perceptions of "justice.") Men's willingness to contribute equally to this workload is held to be important to women for several reasons. Obviously, if men contribute more to the performance of some of the relentless daily tasks of the household, women's leisure time would be comparable to men's. Perhaps of greater significance, however, is the symbolic value of such sharing. Housework has been characterized as "menial work performed by a lower status person for someone of higher status" (Ross, Mirowsky & Huber 1983:821). When husbands share "women's" tasks, on the other hand, neither spouse should feel that he or she is "serving" the other, implying that theirs is a relationship between equals. For these reasons, we expect that *the greater men's relative contribution to the routine tasks of the household, the less likely either spouse is to see housework as unfair to the wife.*

Several studies have indeed found that housework was perceived as unfair to the wife the greater the proportion of routine, or "female-typed," housework done by her (Blair & Johnson 1992; Lennon & Rosenfield 1994; Perry-Jenkins & Folk 1994). Moreover, when husbands' relative contributions to both routine and sporadic housework have been included in analyses, only the former have shown a significant effect on wives' sense of fairness (Blair & Johnson 1992; Lennon & Rosenfield 1994). For a given division of labor in the home, however, other factors are also likely to influence perceptions of fairness.

IDEOLOGY

Through internalizing social norms of gendered behavior, individuals form expectations about their proper roles in marriage. Traditional norms encourage women to be more nurturant than men and to care more about cleanliness and hygiene. Traditional socialization introduces girls — more than boys — to housework at an early age, thereby promoting anticipatory socialization for the later role of "housekeeper." More modern notions suggest, of course, that in the spirit of gender equality, either spouse is equally able to perform both routine and sporadic housework.

We therefore expect that *the more spouses subscribe to an egalitarian sex-role ideology, the more they will tend to see the existing arrangement — in which women do more of the routine tasks — as unfair to wives.* That is, holding constant men's relative contribution to routine housework, we expect that those with more egalitarian beliefs will have higher expectations for men's contributions. Because men's performance typically lags behind expectations in the area of housework, those with greater expectations should be more likely to see existing arrangements as unfair to the wife. Research to date, however, has produced mixed results for the impact of ideology. Some studies have found that wives subscribing to greater gender role egalitarianism see the household division of labor as more unfair to them (Blair & Johnson 1992); while others have found that ideology has no effect (Lennon & Rosenfield 1994). Piña and Bengtson's (1993) data show a more traditional gender ideology to be predictive of a

greater likelihood of being satisfied with the "help and support received" from husbands, but only for wives who are not employed full-time (Piña & Bengtson 1993).

POWER

Lennon and Rosenfield (1994) have recently articulated a social exchange perspective that suggests that key determinants of perceived fairness in household labor are women's alternatives to remaining in the relationship. The fewer a wife's alternatives to the relationship, the more dependent she is on it, and therefore the less power she has with respect to her spouse. Women in these straits have limited expectations for justice. Because they have little leverage with which to induce more cooperation in housework from their husbands (England & Farkas 1986), they instead redefine existing arrangements as "fair" to maintain cognitive consistency between behavior and belief. Moreover, they tend to make social comparisons with other wives who are similarly powerless. Hence, they may see their division of labor as satisfactory in spite of considerable objective inequities in housework, simply because they do not feel entitled to more. Some support for these dynamics has been found in the study by Lennon and Rosenfield (1994). They show that controlling for partners' contributions to housework and sex-role traditionalism, women who perceive fewer options to the current relationship and women whose earnings are below the poverty threshold tend to see the division of labor as more fair to them. This suggests that *the more alternatives women have to the current relationship, the more they will define the division of labor as unfair to them.*

One problem with this hypothesis is that, at any given point in a marriage, the existing division of labor is the end product of a process of negotiation that is largely transparent, particularly in cross-sectional data. As Thompson (1991) suggests, women may not feel that the existing division of labor is unjust if they "accept as appropriate the participatory process by which the outcomes were created" (193). Where women's alternatives should really make a difference is in the negotiations over how much each partner will contribute to household tasks. One would expect that women with more alternatives will have correspondingly greater power to negotiate a balance of housework that is more favorable to them (Blumberg & Coleman 1989). And, regardless of who is favored objectively in the division of labor, wives with more power should be more likely to participate in decisions about the extent of their housework contribution. With this in mind, one could entertain the opposite hypothesis that *existing housework arrangements will be perceived as fairer by the more powerful than by the less powerful wives.* The former are more likely both to have participated in the decision-making process that led to the current outcome and to have effected outcomes consistent with their preferences. Indeed, to the extent that couples experience greater mutual influence in negotiations, they tend to see the resulting behavioral arrangements as more equitable (Scanzoni & Godwin 1990). We will allow the data to determine which of these divergent hypotheses is the more plausible.

EQUITY

Definition

Equity is said to be achieved in an exchange whenever each partner's outcomes are proportional to their inputs (Adams 1965; Sprecher 1986; Walster, Walster & Berscheid 1978). Outcomes are the rewards one receives from an exchange. Inputs are one's own contributions to the exchange (Walster, Walster & Berscheid 1978). In an intimate relationship, a husband's input is usually the wife's outcome, while the wife's input is, correspondingly, the husband's outcome (Cook & Hegtvedt 1983). Formally, equity is achieved whenever (Adams 1965; Jasso 1978)

$$\frac{\mathit{Outcome(Husband)}}{\mathit{Input(Husband)}} = \frac{\mathit{Outcome(Wife)}}{\mathit{Input(Wife)}} \tag{1}$$

Equity across Marital Domains

It is rarely the case that partners either make absolutely no contribution to a particular domain of their relationship or that they make exactly equal contributions to each domain. Instead, partners usually make some contribution to every aspect of the relationship, but one partner's input in a given area usually outweighs the other's. Hence, outcome/input ratios in a given area, such as time spent in routine tasks, are usually unequal. Nevertheless equity can be achieved if an unequal ratio in one domain — such as, again, routine housework — is counterbalanced by an unequal ratio in another domain — such as paid work — in the opposite direction. Therefore, both partners may feel it equitable if the wife, say, does more routine housework but the husband spends more time in paid labor.

Factors Contributing to Equity

Intimate relationships involve the mutual transfer of a wide range of both tangible and intangible rewards. Assessing whether such transfers are balanced is made difficult by the fact that individuals often place different values on the same commodity. At the same time, it is possible to measure outcome/input ratios for a given commodity whenever such commodities are (1) more tangible and (2) measured in the same metric for each partner. With respect to the tangible contributions that are relevant to the total work of a household, three are paramount: (1) contributions to housework, (2) contributions to child care, and (3) contributions to standard of living. Housework entails both routine and sporadic tasks, as outlined above. Child care entails both the additional housework involved in feeding and clothing children and activities connected with child socialization.

Several types of contributions by partners are relevant to the standard of living of the household. These are income, the number of hours in paid labor that is required to obtain that income, and education, which indexes both the status of the household and the cultural milieu in which children are raised. Taking on a second job also indexes a commitment to provide support for the household, beyond what is contributed through one's primary employment. Health status is an additional factor that would be expected to be related to

work performance, whether housework or paid labor, and therefore provides an important indirect contribution to a household's standard of living. When a spouse is in poor health, his or her energy is usually reduced, particularly for the performance of physical labor. Should either partner be impaired, the other partner will be obliged to "pick up the slack" in the total workload of the household. Hence, the relative health status of the partners is important to relationship equity, because the partner in better health may feel that he or she is forced into doing more than his or her "share."

In sum, equity theory leads us to expect that, net of the husband's relative contribution to routine housework, *(1) the greater the husband's contribution to sporadic housework, child care, income, hours in paid labor, education, and health, relative to his wife's and (2) when the husband has a second job but the wife does not, both partners are less likely to see the division of labor as unfair to the wife.*

A few studies have examined the perception of housework fairness as a function of spouses' relative educational or income levels, or wives' hours in paid labor (Benin & Agostinelli 1988; Glass & Fujimoto 1994; Lennon & Rosenfield 1994; Sanchez 1994; Ward 1993). Little support for equity theory has been found thus far. Nevertheless, equity theory leads us to expect some congruence between objective indicators of partners' relative contributions to the domains enumerated above and subjective perceptions of housework fairness. Below we consider why previous research has failed to find such links.

Limitations of Previous Research

There are several limitations in studies of housework fairness to date that either constrain their generalizability or prevent us from establishing which competing theory receives the most support. For example, several studies examine only wives' perceptions of housework fairness (Blair & Johnson 1992; Glass & Fujimoto 1994; Lennon & Rosenfield 1994; Piña & Bengtson 1993), thereby preventing comparisons across gender. Other studies restrict their population to dual-earner couples (Benin & Agostinelli 1988; Lennon & Rosenfield 1994; Perry-Jenkins & Folk 1994), again preventing generalizability to couples with stay-at-home wives. Perhaps more important, with the exception of Lennon and Rosenfield's (1994) study, researchers have typically not included factors representing ideology, power, and equity simultaneously in their models. Consequently, it is not possible to examine the independent contribution of each factor in accounting for perceptions of fairness. Moreover, when equity effects are included, relatively few domains of the relationship have been represented. Of the omitted areas, child care looms as especially important, as husbands may partially balance a low contribution to housework by doing a greater share of child care (Spitze 1988).

Some studies have used as independent variables factors that may themselves be the *effects* of perceived fairness in housework. For example, Lennon and Rosenfield (1994) measure a woman's perceived alternatives to the relationship, or "options," as her perception that, upon separation from the spouse, her standard of living, social life, and career opportunities would improve. It is entirely possible, however, that those who see their division of

labor as unfair will consequently come to see themselves as "better off" without the current spouse. If the causal order of the variables is reversed, or even if there are reciprocal effects, the estimate of the effect of the "independent" variable will be biased. The questionable nature of this measure is even more evident when "options" are used as a predictor of depressive symptomatology. Women who have options to the current marriage are believed to be empowered as a result (Lennon & Rosenfield 1994). Given relationships that are equally happy, one would expect that women with more power will be less depressed. However, Lennon and Rosenfield (1994) found that, controlling for the perceived fairness of housework and marital happiness, women with more options were significantly *more* depressed. These effects call into question the validity of such a measure as an index of women's alternatives to the current marriage.

The present study attempts to redress these problems by (1) examining the perceptions of both husbands and wives, (2) including all couples in which at least one partner is in the work force full-time, (3) including measures of partners' relative contributions to child care, (4) employing measures of ideology, power, and equity simultaneously in models of housework fairness, and (5) employing independent variables with unambiguous causal relationships to perceived fairness.

Methods

THE DATA

The data for this study were drawn from the National Survey of Families and Households 1987-88 (NSFH), a multistage probability sample of 13,008 adults in the noninstitutionalized U.S. population. One individual per household was randomly selected as the primary respondent for face-to-face interviewing. A shorter, self-enumerated questionnaire was given to spouses and cohabiting partners when present. Several subpopulations were oversampled: unmarried cohabitors, recently married couples, single-parent families, families with stepchildren, and households whose heads were African American, Mexican American, or Puerto Rican (Sweet, Bumpass & Call 1988).

Because questions about partners' contributions to the socialization of children were asked only of respondents with children between 5 and 18 in the household, our sample is necessarily limited to that group. We further restricted our sample to households in which the primary respondent was married and living with the spouse, or cohabiting unmarried, and the partner's questionnaire was returned completed. Moreover, because our theoretical arguments are couched in terms of gendered behavior, we excluded same-sex couples. Couples in which either partner was in the armed forces and households in which neither partner was employed full-time were also eliminated. The dynamics of household justice are likely to be different among those who are either part of the military subculture, or among whom neither partner is in the work force full-time. Our remaining sample of 2,153 couples is therefore reasonably representative of nonmilitary heterosexual couples with children among whom at least one partner is in the work force full-time. In that analyses were carried

out separately for husbands and wives, we excluded individual partners with missing data on the dependent variable. Our final sample therefore consists of 2,109 husbands and 2,096 wives.

MEASURES

The Dependent Variable

The perception of fairness in the division of household labor, the dependent variable, was tapped with a single item from the NSFH that asked "How do you feel about the fairness of household chores in your relationship?" Possible response categories were "very unfair to me," "somewhat unfair to me," "fair to both," "somewhat unfair to her/him," and "very unfair to her/him." These responses were coded from 1 to 5, respectively, and constitute a scale with high scores indicating overbenefit. However, for reasons detailed below, a dichotomized version of this variable was also created, with the perception that chores were very or somewhat unfair to the wife contrasted with all other responses.

The Independent Variables

The predictors can essentially be grouped into five categories: partners' relative contributions to routine housework, ideology factors, wives' alternatives, equity factors (including contributions to sporadic housework, as explained below), and controls. Husbands' and wives' contributions to household labor were measured by the number of hours per week that each partner normally spends doing the following nine tasks: (1) cleaning house; (2) preparing meals; (3) washing dishes and cleaning up after meals; (4) washing, ironing, and mending; (5) automobile maintenance and repair; (6) paying bills and keeping financial records; (7) shopping for groceries and other household goods; (8) outdoor and other household maintenance tasks; and (9) driving other household members to work, school, or other activities. Both the main respondent and his or her partner were asked to provide this information; therefore there are two perspectives available on the amount of housework done by each partner, for a total of four sets of responses. Exploratory factor analyses with varimax rotation revealed that, regardless of whose reports were scrutinized, and regardless of whether it was the husband's or the wife's hours in question, two dimensions emerged, with items 1-4 loading primarily on one factor, and items 5-9 loading primarily on the other.

From these considerations we summed the first four items to form a *routine housework* scale and the last five items to form a *sporadic housework* scale.[1] The reliability of these scales varied, depending upon which partner provided the information, but ranged from a low of .54 for females' reports of males' hours in sporadic tasks, to a high of .82 for males' reports of females' hours in routine tasks. Average reliability over the eight scales (four based on each partner's reports) was .71. Husbands' reports of both partners' housework hours in all nine tasks were employed to create the scales for the analysis of husbands' perceptions of housework fairness. Similarly, wives' reports were used to create scales for the analysis of wives' perceptions of fairness. In that it is the respondents' impression of how much time each partner spends doing housework that is likely to influence their sense of justice in the division of

labor, it was important to employ their own perceptions of housework time in each case. Missing values on any item were replaced by the mean for that item, prior to summing.[2]

Two ideology variables were created for the analyses. The first was a *sex-role egalitarianism* scale consisting of six items from the NSFH. The first four asked for the extent of agreement with these statements: (a) It is much better for everyone if the man earns the main living and the woman takes care of the home and family, (b) Preschool children are likely to suffer if their mother is employed, (c) Parents should encourage just as much independence in their daughters as in their sons, and (d) In a successful marriage, the partners must have freedom to do what they want individually. Responses ranged from strongly agree (1) to strongly disagree (5). Items (c) and (d) were reverse-coded so that high scores on these items indicated the most egalitarian beliefs. The other two items asked respondents the extent of their approval of (e) Mothers who work full-time when their youngest child is under age 5 and (f) Mothers who work part-time when their youngest child is under age 5. Responses on these items ranged from strongly approve (1) to strongly disapprove (7), and were also reverse-coded so that the high score represented the most egalitarian response. Because of different response formats, all items were standardized before being summed to create the scale. Scale reliabilities were .66 for husbands and .67 for wives. *Endorsement of housework sharing* was the second ideology factor and was included to tap egalitarianism specifically in the sharing of housework. The single item consisted of responses to the statement, "If a husband and wife both work full-time they should share household tasks equally." Responses ranged from strongly agree (5) to strongly disagree (1). Both husband's and wife's endorsements of sharing were tapped. The foregoing seven items have been used in various combinations to tap gender role ideology in other studies (Blair & Johnson 1992; Lennon & Rosenfield 1994; Presser 1994; Szinovacz & Harpster 1993).

In their direction of influence, these items are considered to be antecedent to perceptions of the fairness of housework, although it is conceivable that seeing housework as unfair in one's relationship might lead one to adopt a more egalitarian stance on gender roles. However, we think it more reasonable that gender ideology precedes evaluations of justice in the marriage. Sex-role preferences are most likely crystallized during late adolescence and young adulthood (Morgan & Scanzoni 1987), as individuals engage in anticipatory socialization for marriage. Moreover, the recognition of injustice presupposes a preexisting standard against which the current arrangement is compared. That standard is a set of beliefs about the proper division of marital roles between partners.

Wives' alternatives to the marriage comprise both subjective and objective dimensions. Because of the previously mentioned problems with investigating the primary subjective measure of dependency in this data set — perceived life change upon separation from the partner — we have elected instead to measure wives' objective alternatives. Scholars have argued that wives have alternatives or "options" to the current marriage to the extent that they are able to financially support themselves outside it (Becker 1991; England & Farkas 1986; Lennon & Rosenfield 1994). To measure this, we include four factors representing the

wife's store of general human capital (Becker 1991; England & Farkas 1986): *income, educational level, hours employed in the labor force,* and *self-assessed health.* We expect that all else being equal, wives with greater income, higher levels of education, a greater commitment to full-time employment — indexed by the number of hours currently employed — and better health will be more able to survive economically outside the marriage than will others, and therefore they have more alternatives to it.

The measure of income was the respondent's total income, excluding income from interests, dividends, and other investments. This variable therefore primarily reflects individuals' earnings from employment. Education was measured in years of formal schooling. Hours currently employed were coded from several questions in the NSFH on employment. Respondents who were currently working for pay were asked how many hours they worked the last week. If that was the number of hours they usually worked, it was used as their hours of employment. If not, hours employed were coded as the typical number of hours worked per week. Those who were not currently employed or who had missing responses for hours of employment were assigned a value of zero on this variable. Health status was based on respondents' reports of the state of their health compared to other people of the same age. Their responses, ranging from "very poor" (1) to "excellent" (5), were treated as interval-level independent variables. Self-reported assessments of health demonstrate good criterion validity, predicting survival over a 12-year period for both sexes (Idler & Angel 1990). Missing values for education, income, and health were replaced by means on those variables.

Husbands' and wives' *relative statuses* on seven factors were included in order to assess the extent to which perceptions of fairness are affected by equity considerations. The first was contributions to *sporadic housework.* This was tapped by the sporadic housework scales described above. One might argue that this is simply part of the total housework load and therefore should be considered on a par with routine housework. However, that would be contrary to a large body of theory and research that suggests that it is only the time that men spend doing "female-typed" tasks that helps to balance out the gender gap in the division of labor (Benin & Agostinelli 1988; Blair & Johnson 1992; Perry-Jenkins & Folk 1994). Our data in fact show that, although men's hours in routine and sporadic housework are about the same (7.3 and 11.4 hours, respectively, according to wives' reports), women spend about three times as many hours doing routine tasks as they spend on sporadic tasks (33 and 11 hours, respectively). Therefore men's time in sporadic housework is not equivalent to women's time in routine housework. Rather, it "counts" toward the fairness of housework only by being considered an "equitable" contribution.

The second through the fifth factors were the human capital factors just enumerated: *income, education, hours in paid employment,* and *self-assessed health.* The sixth factor was *having a second job.* Dummy variables were created to represent whether either the wife or the husband worked at a second job. We consider the wife's having a second job as relevant to equity in the relationship, rather than tapping her alternatives. Although hours of employment index commitment to working outside the home, net of this, having a second job

typically indicates a low-paying primary job rather than a commitment to employment, per se.

The seventh factor was contributions to child care. For households with children, two aspects of child care are paramount. The first consists of the extra housework that must be performed to feed, clothe, and otherwise provide an adequate living environment for children. These chores are already subsumed under the total time spent in routine and sporadic housework. The other consists of activities pertinent to child socialization, such as playing with children, teaching them table manners, helping them with homework, engaging with them in recreational pursuits, and so forth. Child socialization activities were measured in the NSFH by six items asked of all respondents with one or more biological, step-, adopted, or foster children 5-18 years old in the household. Each partner was asked (a) how many days "last week" he/she ate breakfast with at least one of the children, (b) how many days "last week" he/she ate dinner with at least one of the children, (c) how often he/she engaged in leisure activities with the children away from home, (d) how often he/she spent time at home with the children working on a project or playing together, (e) how often he/she had private talks with the children, and (f) how often he/she helped the children with reading or homework. Items (c) through (f) were coded from 1 (never or rarely) to 6 (almost every day).

Factor analyses of husbands' and wives' responses — again employing varimax rotation — suggested a two-factor model for these items, with one factor represented by items (a) and (b) and the second factor represented by items (c) through (f). Therefore we created summed scales for both husbands and wives representing these factors, called respectively *mealtime with children* ($\alpha = .40$ for husbands, .47 for wives) and *child socialization activities* ($\alpha = .75$ for husbands, .74 for wives). Missing values for any item were replaced in each case by the item mean. Some construct validation for these items was provided by examining whether the relative contribution to child care affected respondents' perceptions of the fairness of child care in their relationship. As one would expect, significant relationships were observed between the fairness of child care — coded as unfair to the husband, fair to both, or unfair to the wife — and partners' relative contributions to both mealtime and child socialization. Husbands and wives were more likely to see child care as fair to both partners if their contributions were equal or if the husband did more, than if the wife contributed the greater share of either mealtime or child socialization activities. (Below we discuss in greater detail how partners' relative positions on these seven items were entered into the model.)

Several variables were included in the predictor set as controls because of their potential for confounding relationships between the explanatory variables of primary interest and the dependent variable. For example, older couples, those with longer marriages, and those who are married rather than cohabiting unmarried are likely to be both more conventional in gendered behavior and less likely to see housework as unfair to the wife. Failure to control for them may result in an inflated estimate of the impact of ideology on housework fairness. For these reasons we controlled for marital duration and husband's age in years, cohabiting status (married is the contrast category), and number of children 5-18 years old. To capture race differences, we entered three dummy

variables representing the ethnicity of the couple. The three categories were (1) both partners were black, (2) both partners were Hispanic, and (3) the two partners were both from other ethnic groups — primarily Asian or American Indian — or were each from a different ethnic group. Both partners being white was the contrast category. We also included three dummy variables indicating the relationship of children in the household to each partner. We therefore distinguished stepfather families, stepmother families, and families characterized by other parent-child relationships (primarily double stepfamilies and those with adopted or foster children) from families in which all children were the biological children of both partners (the contrast category). Of the controls, only marital duration was missing for some of the cases, in which case the mean value was substituted.

STATISTICAL MODEL

The perception of housework fairness, our dependent variable, has frequently been treated as an interval scale in other analyses (Glass & Fujimoto 1994; Lennon & Rosenfield 1994). We feel that this may not be the best strategy, for two reasons. First, virtually all scholarly writing on housework suggests that, if anything, the division of household labor is unfair to women. Hence our interest really centers on the degree to which partners see housework as unfair to the wife, rather than the husband. Indeed, an examination of the sample distribution on the dependent variable reveals that fewer than 5% of either husbands or wives consider housework to be unfair to the husband (the exact figures for the unweighted distributions are 3.6% of husbands and 4.8% of wives). Perhaps more important, however, is that the distributions are strongly skewed in the direction of fairness to both partners or unfairness to the wife: more than 95% of responses on this five-level variable fall in the range of 3-5 for husbands and 1-3 for wives. When ordinal variables have few categories, and their distributions are skewed, applying ordinary least squares (OLS) regression may be somewhat problematic. The constant variance assumption required for least-squares estimators to be "best" is violated by categorical data (Agresti 1989), particularly when the distribution across categories is very uneven, as in this case. A consequence is that OLS estimators are inefficient, making for less sensitive tests of individual parameters.

Given these considerations, we employed logistic regression to model the log odds that housework is considered unfair to the wife — as opposed to fair to both or unfair to the husband — as a linear function of the predictor set. At the same time, we also ran the model using OLS with the full five-level dependent variable for comparison purposes. OLS was also employed to diagnose the X-matrix for potential collinearity problems (in SAS or SPSS these diagnostics are available only in the linear regression procedure) and to assess whether our missing value imputation procedure resulted in bias. Comparisons of the OLS and logistic regression results produced no substantive differences. All the significant effects in either type of analysis were in the same direction and supported the same conclusions. However, five more effects were significant across the two (husbands and wives) logistic regressions, that were not significant in the OLS analyses. This tended to confirm the lower sensitivity of

OLS in this instance. For this reason we present the logistic regression results of our multivariate analyses below.

To explore whether collinearity was a problem in our data, we examined the variance inflation factors (VIFs) for each coefficient in the OLS models for both husbands and wives. VIF values above 10 generally indicate collinearity problems (Myers 1986). In our estimated equations, all the VIFs were well under 6. Evidently, collinearity was not severe enough to pose any major problems in our analyses. As part of our diagnostic tests, we also created dummy variables indicating whether any missing values had been imputed for any of the variables for either husbands or wives. Adding these to the models produced virtually no detectable changes in the coefficient values. Nevertheless, it was possible that the impacts of the predictors might be different for those with values imputed, compared to those with complete data on all variables. We checked this by adding a set of terms representing the interactions between whether missing values were imputed values and all other predictors, to the base model. For both husbands and wives, the set of interaction terms was very insignificant ($p > .4$). It appears that imputed missing values did not substantially affect our results. Our multivariate models are therefore presented without controls for imputation. All inferential analyses (including the bivariate results discussed below) have been weighted to correct for oversampling. Weights have additionally been modified to sum to the unweighted number of cases.

MODELING EQUITY ACROSS MARITAL DOMAINS

Authors of previous studies have employed a number of strategies for tapping partners' relative contributions to the marriage, including ratios (Ward 1993) and logged ratios (Presser 1994) of partners' resources and a given partner's proportionate contributions in different areas (Lennon & Rosenfield 1994). Each strategy presupposes a specific conceptualization of how equation 1 above is to be modified to reflect balance across the multiple domains of marriage. Of the three techniques just mentioned, we prefer an additive model of logged ratios of partner's resources. In contrast to proportionate contributions, they imply a very straightforward extension of equation 1. Formally, if O_{jh} and I_{jh} are the husband's outcome and input, respectively, in the jth domain of the relationship, and O_{jw} and I_{jw} are the corresponding outcome and input of the wife in the jth domain, then we can envision equity obtaining across the domains of a relationship if

$$\left(\frac{O_{1h}}{I_{1h}}\right)\left(\frac{O_{2h}}{I_{2h}}\right)\cdots\left(\frac{O_{Jh}}{I_{Jh}}\right)=\left(\frac{O_{1w}}{I_{1w}}\right)\left(\frac{O_{2w}}{I_{2w}}\right)\cdots\left(\frac{O_{Jw}}{I_{Jw}}\right) \tag{2}$$

That is, equity is achieved whenever the products of the outcome/input ratios across the $j = 1, 2, \ldots, J$ domains of the relationship are the same for husbands and wives. Taking natural logs of both sides, equation 2 implies

$$\sum_{j=1}^{J} \log\left(\frac{O_{jh}}{I_{jk}}\right)=\sum_{j=1}^{J} \log\left(\frac{O_{jw}}{I_{jw}}\right) \tag{3}$$

This formulation suggests that equity is obtained to the extent that the sums of logged husband-wife ratios of contributions to each key domain of the relation-

ship approach equality across partners. In terms of the fairness of housework, this formulation also suggests that the greater the right side of equation 3, and the lower the left side, the less likely either partner will be to perceive housework as unfair to the wife.

An example will help to clarify how equations 2 and 3 capture equity/inequity across domains. We assume that husbands' inputs are wives' outcomes, and vice versa. Suppose that the husband spends 50 hours per week in paid labor, does 10 hours of housework, has a college degree, and makes $50,000 per year. His wife, on the other hand, spends 40 hours in paid labor, does 30 hours of housework, has 3 years of college, and makes $30,000 per year. The left side of equation 2 is: (40/50) (30/10) (15/16) (30,000/50,000) = 1.35, while the right side is: (50/40) (10/30) (16/15) (50,000/30,000) = .741. The exchange is clearly imbalanced in favor of the husband. If, on the other hand, his income were $67,500, both sides of equation 2 would equal one, and the exchange would be equitable.

Miles's (1987) review of the equity formulas proposed by various theorists enumerates a number of criteria that an equity formula should satisfy to be valid. Equation 2 satisfies those criteria provided that both outcomes and inputs in each ratio are nonnegative and inputs are bounded away from zero. Both conditions are satisfied in this study. None of the resources used to create ratios can logically take negative values. For resources that could take on a value of zero (e.g., hours in paid labor), one-half was added to the numerator and denominator of the ratio prior to taking the log to prevent the occurrence of undefined logs or undefined ratios. Equation 2 also effectively allows combining outcomes or inputs measured in different units, a problem that plagues other formulations (Miles 1987). Because the same units of measurement cancel in the numerator and denominator of ratios, they constitute a unitless metric. Although Farkas and Anderson's (1979) equity integration formula also proposes to take account of multiple inputs, it is quite cumbersome compared to equation 2. Moreover, it is not clear how their formula is to be extended to the case of multiple outcomes and multiple inputs simultaneously (Miles 1987). In our formulation, on the other hand, that extension is straightforward.

We employ logged husband-wife ratios of sporadic housework hours, mealtime with children, child socialization activities, income, hours in paid labor, and health status to measure equity in these domains. Because relative contributions to routine housework are also part of the overall equity equation, they were also tapped using the log of the husband-wife ratio. An examination of the logged ratio of partners' educational levels revealed an extremely leptokurtic distribution with little variance and only a few observations reflecting large educational differences. We therefore assessed partners' relative education with dummy variables indicating whether either the husband or the wife had more education (equal education was the contrast). As previously noted, dummy variables were also used to indicate whether the husband or the wife had a second job. Finally, for each of the logged ratios, as well as relative educational standing, we also included in the model the wife's corresponding contribution in raw units. This allows us to separate the effects on housework fairness due to wives' absolute contributions across domains from those due to

partners' *relative* contributions. Descriptive statistics for all variables in the analysis are shown in the Appendix.

Results

BIVARIATE ASSOCIATIONS

Before proceeding to the evaluation of the multivariate models, we briefly consider some bivariate findings of interest. In Table 1, we present a comparison of the proportions of husbands and wives who consider housework to be, alternately, unfair to the wife, fair to both partners, and unfair to the husband. For this analysis we look only at the 2,054 couples in which both partners responded to the question on fairness. Because these are dependent proportions, we test for gender differences using McNemar's chi-squared test (Agresti 1990). It is evident that wives are more likely than husbands to see housework as unfair to women. About 36% of wives as opposed to 30% of husbands give this response. Correspondingly, husbands are more disposed to see housework as fair to both (66.3%) than are wives (59.4%). Husbands and wives appear to be in harmony on whether housework is unfair to husbands: only 3.7% of husbands and 4.6% of wives give this response, an insignificant difference.

Tables 2 and 3 show the relationship between husband's relative contributions to each type of housework and the perceived fairness of housework. The association is shown from two different perspectives. Table 2 is similar to Table 4 in Lennon and Rosenfield (1994).[3] As in their table, ours examines the conditional distribution of the husband's relative contribution to housework, given husbands' and wives' reports of housework fairness. Our measure of relative contribution is the average ratio of husband's and wife's hours of housework. In this case, perceptions of fairness are — incorrectly — being treated as the "independent" variable. (Customarily, one examines the conditional distribution on the dependent variable, given levels of the independent variable.)

We see from the table that, among both husbands and wives who see housework as fair to both partners, husbands perform, on average, between 11 and 22% more of the sporadic chores than wives do (the ratios are 1.108 using wives' reports, and 1.217 using husbands' reports). Among those who see housework as unfair to the husband, husbands do between 13 and 34% more of the sporadic chores. Among those who see housework as unfair to the wife, husbands only do 85 to 95% as much sporadic housework as their wives. Lennon and Rosenfield (1994) correctly conclude from this that both women and men appear to believe that men should do more than half of the male-typed tasks.

Turning to the routine tasks, we note the striking imbalance between men's and women's actual task performance, regardless of how fair it is considered to be. For example, both husbands and wives who see housework as unfair to husbands estimate that men only do between 36 and 39% as much as women. Those who say it is fair to both estimate men's performance to be only 19% of women's. And those who see housework as unfair to the wife see men as doing only 13 to 14% of the housework that women do. Lennon and Rosenfield's

conclusion from these findings is that they reflect "a general *acceptance of an unequal division of housework,* with women spending many more hours on the routine, time-consuming, traditionally female tasks" (Lennon & Rosenfield 1994:520-21, emphasis added).

To show why this conclusion is ill-advised, we present Table 3, which correctly shows the conditional distribution on housework fairness, given husbands' and wives' relative performance of housework. For this analysis, the ratios of husbands' to wives' housework hours have been collapsed into three categories: the husband does more housework, both partners do the same amount, and the wife does more housework. Because so few partners are exactly equal in housework hours (e.g., only 14 are exactly equal in routine housework, according to wives), we have considered contributions to be equal if the husband's contribution is within 10% of the wife's (i.e., the ratios are between .9 and 1.1). In our sample, in which wives perform, on average, about 33 hours of routine housework per week, this amounts to an average weekly gender difference of 3.3 hours of routine housework either way, or fewer than 30 minutes per day. Other researchers have considered the division of labor to be "equal" as long as the gender difference is less than one hour per day (e.g., Piña & Bengtson 1993).

Table 3 shows that the likelihood of saying that routine housework is fair to both partners is *highest* among couples in which both partners do approximately the *same* amount of housework and lowest when the *wife* does more. The findings with respect to sporadic housework confirm the conclusions from Table 2; that is, partners are most likely to see housework as fair when the husband does more of these tasks. Why are the conclusions about partners' expectations for fairness so different for routine housework, when Table 3 rather than Table 2 is examined? In that women do more of the routine tasks in more than 93% of the couples in the sample, examining the conditional distribution of partners' relative contributions to housework across categories of fairness accurately reflects the gender gap in housework *performance,* regardless of the acceptance (i.e., perceived fairness) of the arrangement. However, examining the perception of fairness, conditional on housework performance (as in Table 3), it

is clear that both husbands and wives are most likely to *accept* the situation as fair when housework is equally apportioned.

MULTIVARIATE FINDINGS

Tables 4 and 5 present the results of logistic regressions of the log odds of seeing housework as unfair to wives on the predictor set, separately for husbands and wives. To conserve space, we show only the significant predictors and exclude the intercept. (Full tables are available from the authors upon request. See the Appendix for a listing of the complete predictor set used in the multivariate analyses.) Shown at the bottom of the tables are chi-squared tests for the set of predictors in the model; both are highly significant. We also show McKelvey and Zavoina's (1975) R^2 analog for logistic regression, denoted by $\hat{R}^2$. This measure is an estimate of the proportion of variance that would be accounted for by the model in unfairness to the wife, if the latter were measured as a continuous variable. These values are .21 for husbands and .16 for wives.

Results for Husbands

Of the controls, husbands' age, the race of the couple, and the nature of the relationship between the children and each partner all have significant effects on husbands' perceptions of whether housework is unfair to wives. The older the husband, the less likely he is to consider housework to be unfair to his partner. In that gender-role attitudes are controlled in the analysis, this effect is over and above the association of increasing age with gender-role traditionalism. Black and Hispanic men are less likely than whites to consider housework as unfair to their wives. In contrast to couples in which children are all the biological

the wife) results in about a 23% reduction (100 [.767 - 1]) in the odds that housework is seen as unfair to the wife. It is interesting that his relative contribution is what is important: controlling for the logged routine-hours ratio, husbands' reports of how many absolute hours the wife spends in routine housework have no significant effect on fairness.

Of the ideology factors, both husbands' general sex-role egalitarianism and their endorsement of housework sharing have significant effects. The more generally egalitarian the husband, the more he sees housework as unfair to his wife. However, controlling for other ideology variables, the more that he

endorses sharing in housework, the less likely he is to report that the existing arrangement is unfair to his partner.

Of the wife's human capital factors, only her education is significant. Specifically, each additional year of schooling the wife has completed increases the odds that her husband will see housework as unfair to her by about 12%.

A number of the equity factors have significant effects. Their interpretation will be facilitated by keeping in mind that, because all logged ratios have husbands' contributions — or inputs — in the numerator of the ratio, the equity equation for husbands is the inverse of equation 2. Therefore we expect that the greater the husbands' inputs, relative to his outcomes, in areas other than routine housework, the less likely he will see housework as unfair to his wife. These predictions are borne out for inputs to sporadic housework and child socialization activities and partners' relative health. Each unit increase in the logged sporadic-hours ratio decreases the odds that he will see housework as unfair to his wife by about 29%. Similarly, the more he engages in child socialization activities and the better his health, relative to his wife, the less likely he is to see housework as unfair to her. The main effect of the wife's frequency of child socialization is additionally significant: the more often she engages in these activities, the less likely he is to see housework as unfair to her. Relative education is also significant, but in a direction contrary to equity. Husbands with more education than their wives are more likely than those with the same amount of education to see housework as unfair to their wives.

Results for Wives

The results for wives parallel those for husbands in many respects. Along with Hispanic husbands, Hispanic wives are less likely to see housework as unfair to them than are white wives. Similarly, wives with adopted or foster children in the household or those in double stepfamilies are less likely to view housework as unfair to them than are those with biological children.

Husbands' relative contribution to routine housework has the same effect in the wives' as in the husbands' equation: The greater his relative contribution, the less likely she is to see housework as unfair to her. Once again, the absolute number of hours she spends in routine housework has no effect on her evaluation of housework justice.

Of the ideology factors, only the endorsement of housework sharing by each partner has a significant effect on housework justice among wives. The more the wife endorses sharing, the more likely she is to see the existing arrangement as unfair to her. Controlling for her egalitarianism in this area, however, the more the husband endorses sharing, the less likely she is to see housework as unfair.

Wives' human capital factors have little effect on their perception of housework justice, with the exception of their self-assessed health. Yet the effect is contrary to expectation: The better a wife's health, the less likely she is to view housework as unfair to her.

Several equity factors are again significant. The husband's relative contribution to sporadic housework, mealtime with children, hours in paid employment, and relative health compared to his wife's all have the expected effects on the wife's perception of housework fairness. Each unit increment in the logged sporadic-hours ratio reduces the odds that she sees housework as unfair to her

by about 42%. Indeed, a test of the equality of coefficients for routine and sporadic housework reveals that for wives (but not husbands), husbands' contributions to sporadic housework have a significantly ($p < .002$) stronger effect on wives' perceptions of fairness than husbands' contributions to routine housework. For husbands, the men's relative contribution to child socialization reflected the impact of equity. Among wives, on the other hand, it is contributions to mealtime with children that is important. The more meals he has with the children, relative to his wife, the less likely she is to see housework as unfair. Similar to findings for husbands, the better his health compared to hers, the less likely she is to say that housework is unfair to her. Although partners' relative contributions to paid employment were not significant for husbands, the effect is significant for wives. The greater the husband's number of hours in paid labor, relative to his wife's, the less likely she is to see housework as unfair. Finally, wives' frequency of child socialization has the same effect as in the equation for husbands: The more frequently she engages in child socialization activities, the less likely she is to say that housework is unfair to her.

Discussion

Net of partners' relative contributions to the routine, or traditionally "female," work of the household, our study finds stronger support for ideology and equity than for wives' human capital as determinants of housework justice. The only index of wives' human capital having the expected effect was wives' education: Husbands of more educated wives were more likely to see housework as unfair to their partners. No such effect was observed, however, for wives. Among the latter, only a wife's health was predictive of housework fairness, but in the opposite direction to that expected: Wives in better health were less likely to say that housework was unfair to them.

The failure of factors tapping wives' general human capital to have much effect on perceptions of housework fairness for either partner was not entirely unexpected. We have argued that wives' alternatives to the marriage may have countervailing effects on judgments of fairness of the existing division of labor. On the one hand, wives with more alternatives should have greater leverage in the relationship with which to negotiate a more favorable division of housework (see England & Farkas 1986 for arguments supporting this reasoning). This means that they should be more likely to see the outcome as fair. On the other hand, their expectations for equality may well be higher, and hence they are also likely to judge any given arrangement as less fair (see Lennon & Rosenfield 1994 for an elaboration of this argument). Unfortunately, we have no information on a crucial element of wives' options: their ability to attract other mates. Although wives with more human capital may well be able to support themselves outside the marriage, most men and women do not want to spend their lives alone. Either partner's personal or physical attractiveness would be expected to exert a powerful influence on their ability to choose other partners and hence to add leverage to their negotiations in the marriage (Blumberg & Coleman 1989; England & Farkas 1986; Walster, Walster & Berscheid 1978). Indeed, South and Lloyd's (1995) recent work on marital dissolution suggests

that almost a third of recent divorces were preceded by infidelity on the part of at least one partner. They further found that, net of individual characteristics, the probability of any marriage ending in divorce is enhanced when either the husband or the wife encounters a surplus of alternative partners. The lack of any measures in the NSFH with which to assess individuals' access to alternative partners prevents further investigation of this issue with these data. Nevertheless, future research on couples' negotiations over key issues such as housework should attempt to include measures of partners' relative access to other mates. Such bargaining "chips" may provide either partner with enhanced power to achieve desirable outcomes.

Of the other factors hypothesized to affect the perception of justice in housework, ideology was significant for both husbands and wives. More egalitarian husbands tended to see housework as more unfair to their wives. The more wives endorsed the sharing of housework, the more they saw the existing arrangement as unfair to them. However, the more husbands agreed that housework should be equally shared, the less both partners saw housework as unfair to the wife. These patterns suggest that the motivation behind husbands' housework is a key factor in partners' evaluations of their division of labor. To the extent that husbands perform housework because they believe in sharing it, rather than because they have been coerced, both husbands and wives are more likely to accept this work as fairly distributed. This is consistent with literature suggesting that husbands' housework is prized by wives primarily for its symbolic value in equalizing the status of the partners (Hochschild 1989; Piña & Bengtson 1993; Ross, Mirowsky & Huber 1983). Housework performed willingly, rather than grudgingly, by husbands would necessarily have greater symbolic value to both partners.

Similarly, several variables tapping objective equity were significant. The greater the husband's relative contribution to sporadic chores and to child care, and the better his health relative to his wife's, the less likely either partner was to say that housework was unfair to the wife. Moreover, the greater the disparity between the time husbands spent working and that spent by their wives, the less likely women were to say that housework was unjustly apportioned. Of the equity factors that did not have the expected effects for either husbands or wives, education and income are especially interesting. These factors could also be said to tap spouses' relative power in the relationship. Were they to have been found significant in the expected direction, one could argue that power differentials, rather than equity, are driving the results. In contrast, it is the factors having to do with relative contributions to the labor required for the sustenance of the household that have the expected effects: sporadic housework, child care, health, and hours in paid employment. Because these factors have little to do with power differentials, the case for equity is perhaps that much stronger.

Nevertheless, there were some unexpected findings. Both partners were less likely to see housework as unfair to women the more hours the latter spent in child socialization activities. However, we see this as indicative of the fact that activities with children are a valued activity for both partners (Thompson & Walker 1989). The time that wives get to spend with children doing enjoyable activities — having private talks, taking them to recreational events, and so

forth — may very well be seen by both partners as compensating for the less interesting work of the household.

More troubling for the equity hypothesis was the fact that husbands with more education than their wives were *more* likely to see their wives as unfairly burdened with housework. This is clearly contrary to the expectation that superior education would act as an input for men that compensates for less effort in housework. Rather, it appears that status differences in favor of husbands make them more uneasy with the typical setup in which wives are shouldering most of the household chores. As the performance of housework for another's benefit has been characterized as servile (Ross, Mirowsky & Huber 1983), these husbands may be reacting to their wives being so stigmatized. This, however, suggests a much more complex interplay between outcome/input ratios and relationship dynamics than was originally hypothesized. Hochschild (1989) has already suggested such an interplay via a "balancing" strategy among wives. She observed that wives in her study with incomes superior to their husbands' balanced such a threat to their partner's status by doing *more* than their normal quota of housework. This, too, is contrary to equity principles, which predict that such wives would correspondingly *reduce* their housework load. In either case, equity considerations do not appear to operate in an affective vacuum. Perceptions of, and feelings about, the meanings that one's partner attaches to exchanges in an intimate relationship appear to intrude upon a straight calculation of one's own gain and loss. Future research needs to provide more assessments of such considerations so that the processes involved in exchanges among intimates can be better untangled.

The impact of both ideology and equity considerations in our models also suggests that equity considerations alone do not inform the perception of fairness in intimate relationships. In this sense, our findings support previous critiques of the rational choice model of negotiation (see especially Marini 1992). Exchange theorists tend to view dyadic bargaining as occurring on a level playing field, in which all partners have equal information, and in which choices are relatively unconstrained except by their potential for evoking reward (England & Farkas 1986; Kelley & Thibaut 1978; Marini 1992; Thibaut & Kelley 1959). To the extent that perceptions of justice in housework are channeled by gender-role ideology, partners may be induced by internalized cultural norms to accept arrangements that are not in their best interests. Bargaining will typically cease when each partner feels that he or she has extracted maximum profit from the exchange (Kelley & Thibaut 1978). As long as women, in particular, are taught that they have the primary obligation for housework, they will already come to the "bargaining table" with lowered expectations for "profit." Under such conditions, they will come to accept housework arrangements that are imbalanced in favor of men as "fair" (see Bielby & Bielby 1992 for a discussion of the parallel effects of ideology in constraining couples' negotiations over moving for career advancement). More work needs to be done on the ways in which negotiations over the household division of labor are constrained by partners' acceptance of such ideologies.

Some limitations of this study should be addressed in future research. First, we have assumed that there is a recursive causal relationship between the actual performance of housework and the perception of housework justice. Yet what

we have examined is the relationship between the perception of housework justice and *reports* of housework performance. It is entirely possible that these two elements, as measured, are nonrecursively linked. That is, reports of housework hours influence perceptions of justice because they reflect the actual time spent in housework. But perceptions of housework justice may also distort partners' recall of the time each spouse has actually spent doing housework. Thus, partners who see housework as unfair to the wife may recall the husband contributing fewer hours than he actually did, and vice versa. This problem, of course, is not unique to our study but rather characterizes all studies that link reported housework to its perceived fairness. Having spouses keep diaries of daily time spent in various household tasks (as, for example, in Coverman & Sheley 1986) is one way of minimizing this problem.

Second, we have touched above on the executive component of housework responsibilities. Unfortunately, the NSFH contains no information about who is responsible for the planning and supervision of housework. We were therefore not able to ascertain whether sharing the responsibility for overseeing household upkeep is a factor in judgments that housework is fairly divided. Other research suggests that women are especially troubled at being left in charge not only of doing most of the housework, but also of sensing when and if it needs to be done (Rubin 1976, 1983). As this is a major aspect of housework on which men and women are likely to differ dramatically, it should be included in future studies.

Finally, our approach to housework and child care has been limited in its disregard for individual preferences. Such a simplistic approach was dictated by the constraints of the data. The NSFH did not ask respondents the degree to which each household task or activity with children was pleasant or distasteful. Certainly the value to the partner of one's contribution to household work or child care would be reduced to the degree that it is intrinsically rewarding, and enhanced to the degree that it is not. Previously we speculated that such considerations are responsible for the finding that women's time in child socialization is unexpectedly linked to a lower likelihood that either partner will see housework as unfair to her. In making this speculation, we have assumed that both partners value time spent with their children in constructive endeavors. However, lacking measures of the relative preferences for each activity, such a speculation is, for the moment, unsupported. Scholars engaged in subsequent studies of housework fairness should ensure that assessments of individuals' preferences are included in their research designs.

Notes

1. Although some of the tasks that we have labeled sporadic, for example, shopping or driving, may be done fairly regularly, tasks 1-4 are clearly the most time-consuming tasks for wives in the sample and are therefore distinguished as the "routine" tasks. According to both partners' reports, wives spend upward of five and a half hours per week doing each of these. In contrast, shopping — the next most time-consuming chore for women — takes up only three-and-a-half hours in the typical week.

2. Other researchers have usually recoded extreme values reported for housework hours so that these sums are not above some reasonable value, such as 84 hours (Presser 1994) or 100 hours (Perry-Jenkins & Folk 1994) per week for employed persons. This has not been done here

APPENDIX: Means and Standard Deviations for All Variables in the Multivariate Analyses[a]

	Mean	Std. Dev.
Dependent variables

Wife's endorsement of housework sharing	4.246	.738

because our interest is in the impact on housework fairness of the male's *relative* contribution to housework, as assessed by the logged ratios of male to female task hours. Moreover, the males' reports of each partner's housework hours are used in the equations for males, and females' reports are used in equations for females. We assume further that the tendency to report exaggerated hours in housework will be randomly distributed across genders, and should apply equally to hours reported for either partner. For this reason, the ratios of male-to-female hours should not be biased, given that overestimates in the denominator should counterbalance overestimates in the numerator, for either gender.

3. Our definitions of routine and sporadic tasks differ somewhat from what Lennon and Rosenfield refer to as the "female" and "male" tasks. Their "female tasks" add shopping to the routine tasks enumerated above, while the "male" tasks include only paying bills, outdoor tasks, and automobile maintenance.

Physical Impairment and the Diminishing Effects of Income*

JOHN MIROWSKY, *Ohio State University*
PAUL NONGZHUANG HU, *Ohio State University*

Abstract

The effect of income on physical impairment steepens at lower levels of income. Why? Two national surveys show the following. Basic needs: the level of impairment and its rate of increase rise sharply as household income drops below the 20th percentile; above that level greater income has little effect; economic hardship explains much of the pattern. Resource substitution: education reduces the association between impairment and low income, but low education often coincides with low income. Compounding problems: impairment suppresses the rise of income, concentrating economic and health problems over time. Status lifestyle: Exercise increases with income but explains little of the association with impairment. Social background: stable traits that affect both income and impairment account for about half of their association, with education the largest factor.

Previous research shows that income is associated with a greater sense of health and well-being and with lower psychophysiological distress, lower functional impairment, and lower risks for morbidity and mortality (Broom 1984; Gold & Franks 1990; Haghighatian & Baer 1990; Hay 1988; Hirdes et al. 1986; Maddox & Clark 1992; Mirowsky & Ross 1989; Pappas et al. 1993; Rogers 1992; Williams 1990). Income provides the means to improve health through better living conditions, more accessible and higher quality medical care, and reduced stress and anxiety. Less clear is the exact form of the relationship between income and health. Most studies implicitly assume that the association is linear: a unit

* *We thank Catherine E. Ross for use of the data from her survey of Work, Family and Well-Being that was funded by the National Science Foundation (SES-8916154). Sampling, pretesting, and interviewing were conducted by the Survey Research Laboratory of the University of Illinois. Data for the National Survey of Personal Health Practices and Consequences were collected by the National Center for Health Statistics (NCHS), U.S. Department of Health and Human Services. They were made available, in part, by the Inter-University Consortium for Political and Social Research (ICPSR). Mirowsky and Hu are equal coauthors of this report.* *Address communications to John Mirowsky, Department of Sociology, Ohio State University, 300 Bricker Hall, 190 North Oval mall, Columbus, Ohio 43210-1353 or e-mail: mirowsky.1@osu.edu.*

 Social Forces, March 1996, 74(3):1073-1096

increase in income produces a unit improvement in health. Recent evidence challenges this assumption. Differences or changes in income may influence health more strongly among those with marginal or modest incomes than among those with affluent ones. House et al. (1990) find only slight health differences associated with greater income above $20,000 but markedly worse health as incomes drop below $20,000 (at or near the poverty levels). Diener et al. (1993) find a similar nonlinear effect of income on subjective well-being using U.S. national data. Epelbaum's (1990) review of "sociomonetary relationships" between measures of income or wealth and measures such as rates of morbidity, mortality, and health finds curvilinear patterns that suggest diminishing effects of greater income. Such findings strongly suggest that the effect of additional income on health diminish as the levels of income rise.

As Angell (1993) points out, at this stage we do not know with any certainty that the protective effects of higher income apply at the upper levels of privilege. We pose three questions. First, is there really a diminishing effect of greater income on health? Second, is there a threshold below which greater income improves health and above which it does not? Third, what, if anything, causes the effect of income to diminish at the higher income levels?

Although a number of findings suggest diminishing effects of greater income on health (e.g., Epelbaum 1990; House et al. 1990), relatively few suggest why the effect should taper off at higher levels. The most obvious explanation refers to the fundamental reason why income might effect health in the first place. The *basic-needs hypothesis* says income improves health because it helps individuals meet universal human needs (Williams 1990). Once needs are met, greater income can have no more effect. Indeed, one may define poverty as the lack of means necessary for physical well-being — as the inability to meet basic needs for food, shelter, clothes, and care. The higher one's income, the more likely these needs will be met. At some level of income most people can afford adequate food, housing, and clothes. Reasonably good medical care might require somewhat higher income than other needs, but at some level of income most people have what they need. The effect of greater income on health diminishes as it rises beyond the amount needed to provide the essentials. Thus, the basic-needs hypothesis implies two things. First, it implies the existence of a critical point — a "poverty line" defined in terms of health. Below the line greater income improves health; above the line it does not. Second, it implies that economic hardship mediates a large fraction of the association between low income and poor health: In the absence of difficulty paying bills and buying necessities like food, clothes, or medicine, low income does not translate into poor health.

The *resource-substitution hypothesis* supplements the needs hypotheses. It says that income is only one of the resources that help people meet their health requirements. Greater income has more impact in the absence of other resources, and, conversely, less impact in their presence. All the useful resources tend to be scarce at the bottom of the socioeconomic ladder and abundant at the top. The scarcity of other resources makes the health of low-income people more sensitive to increases in income. The abundance of other resources makes the health of high-income people less sensitive to increases in income.

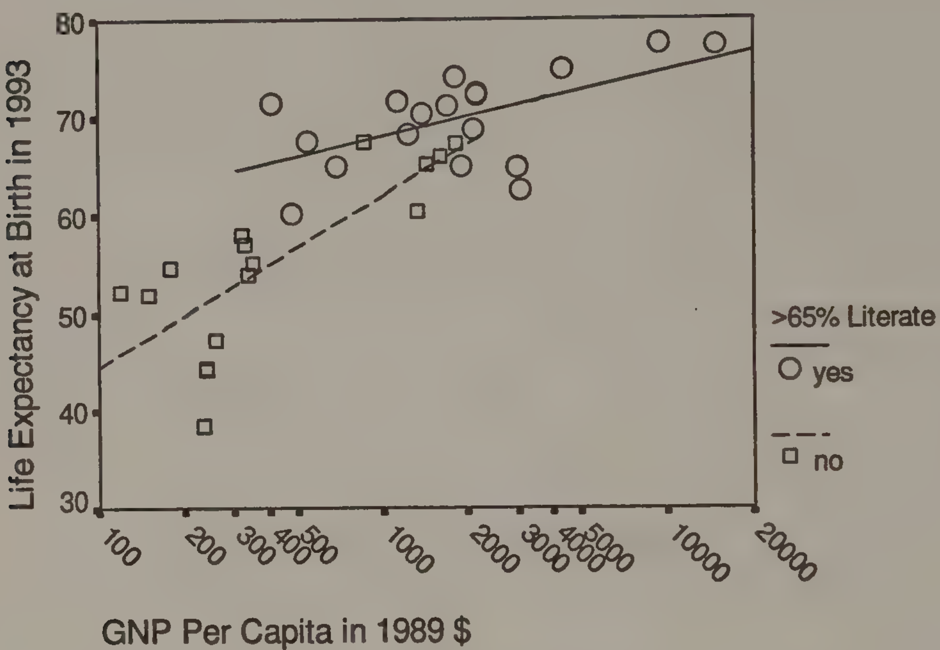
Cross-national data on life expectancy at birth suggests that education may operate as an alternative resource for health (Mosley & Cowley 1991; Sen 1993). A life expectancy of 65 years or more generally coincides with a Gross National Product (GNP) per capita above $2,000. However some countries with low GNP per capita but relatively high literacy rates also have life expectancy of 65 years or more. Sri Lanka stands out among the countries in this category. With an adult literacy rate of 87.1%, Sri Lanka has a life expectancy of 71.5 years despite having less than $500 of GNP per capita (U.S. Bureau of the Census 1993). Life expectancy and GNP come from the U.S. Bureau of the Census International Data Base (U.S. Bureau of the Census 1993). Literacy rates come from the United Nations Educational, Scientific and Cultural Organization (Hoffman 1991). Figure 1 plots the life expectancy at birth by GNP per capita for 34 countries with populations of 5 million or more that report literacy rates. The figure also shows the OLS regression lines for countries with low and high literacy (below and above the 65% level). Predicted life expectancy increases more rapidly with GNP for the lower-literacy countries than for the higher-literacy ones. GNP and literacy appear to act as alternative inputs to life expectancy.

U.S. survey data also suggests that education and income may substitute for each other as alternative resources. Ross and Huber (1985) find that income has a weaker negative association with economic hardship at higher levels of education. Low income raises the average frequency of difficulty paying for needed food, clothing, and medical care, but *less* so at successively higher levels of education. Higher income reduces the risk of economic hardship the most for the poorly educated. Presumably the better educated know how to meet their household needs with less income. Of course, higher income often implies higher education. Implicitly, then, an increment in income reduces economic hardship less among the prosperous than among the poor, because the prosperous tend to be better educated. In essence, higher education makes each additional dollar less necessary for meeting needs. Because of the positive correlation between education and income, additional dollars reduce economic hardship less at higher levels of income. The same may be true for health outcomes.

The basic-needs and resource-substitution hypotheses focus on probable mediators and moderators of income's effect on health, but they ignore the possibility of dynamic feedback. The *compounding-problems hypothesis* argues that processes of social selection based on health concentrate the people with poorest health at the lowest levels of income. Poor health reduces income and low income reduces health. Regardless of which problem begins the cycle, one precipitates the other. Low income increases the risk of health problems that simultaneously magnify economic hardship and hamper efforts to escape poverty. Over a period of time, low initial income increases the rate at which health problems emerge; and initial health problems reduce the rate at which income rises. Over a series of periods the problems compound, concentrating poor health among those with low income and low income among those with poor health. Thus, the compounding of economic and health problems might create an increasing gradient of poor health at lower and lower levels of income.

The *status-lifestyle hypothesis* suggests another explanation of income's diminishing effect on health. People need physical activity in order to keep fit.

FIGURE 1: Life Expectancy by GNP and Literacy



In the U.S. today, working, commuting, and shopping require little physical effort, making exercise a leisure activity. Among U.S. adults the average amount of weekly exercise increases with socioeconomic status — particularly with education but also with income (Hayes & Ross 1986). Perhaps a daunting environment and the struggle to make ends meet make it hard for many lower-income people to exercises regularly. Perhaps exercise operates as a modern form of conspicuous consumption, or as a public display of proper and prestigious attitudes. Or perhaps exercise reflects an orientation toward the future — a biological savings plan with sacrifices made today for benefits expected in the future. Whatever the reason for the positive correlation between income and exercise, the correlation may contribute to the concentration of poor health at the lowest levels of income.

A final hypothesis notes that income and health may have common social precursors that create correlation between them. The *social-background hypothesis* says that sex, race, marriage, and education account for much of the association between income and health. Females, nonwhites, the unmarried and the relatively uneducated tend to have both low income and poor health. To the extent that these aspects of social background have nonlinear effects on either income or health, they could produce a correlation that is stronger at low levels of income than at high ones. To take a simple example, suppose that racial differences in health and income account for the correlation. Blacks have more health problems than whites; the percentage black increases sharply toward the bottom of the income distribution; thus the level of health problems rises sharply toward the bottom of the income distribution. As always, the possibility

of spurious association needs to be examined. In this case, though, one should not think of the spurious component as a false and irrelevant correlation to be excised and then ignored. Suppose that social background accounts for a substantial fraction of the total correlation between income and health. If so, the finding would reveal part of the means by which poor health becomes concentrated among persons with low income.

SUMMARY

Does the incremental effect of income on health diminish at higher levels of income? And if so, why? We will examine the profile of the relationship and test several hypothesis, using physical impairment as our index of health (see the measurement section for details):

(1) The *basic-needs hypothesis* says that higher income predicts lower impairment up to a point but not beyond *and* that adjustment for economic hardship substantially and significantly reduces the negative association between income and impairment;

(2) The *resource-substitution hypothesis* says that education reduces the strength of the association between income and physical impairment such that increments in income have diminishing effects at higher levels of income because of the coinciding higher levels of education;

(3) The *compounding-problems hypothesis* says that income reduces the rise of impairment over time *and* that impairment reduces the rise of income over time;

(4) The *status-lifestyle hypothesis* says that adjusting for exercise substantially and significantly reduces the nonlinear association between income and impairment, and;

(5) The *social-background hypothesis* says that adjusting for sex, race, marriage, and education substantially and significantly reduces the nonlinear association between income and impairment.

Method

SAMPLES

We use two data sets to enhance the generalizability of the results and to compare cross-sectional with follow-up results. The data come from two telephone surveys of national probability samples of U.S. households. We chose the data sets because each contained adequate and comparable measures of impairment, income, economic hardship, and exercise, as well as measures of education, sex, race, marriage, and age. Each survey has its strengths and weaknesses, with the strengths of one covering the weaknesses of the other. The Work, Family, and Well-Being (WFW) survey has particularly good measures of income and economic hardship (described below), but the data are cross-sectional, and the index of exercise has only two items. The Health Practices (HP) survey has weaker measures of income and economic hardship than the WFW survey, but it has follow-up interviews and a more reliable index of exercise.

The 1990 U.S. Survey of Work, Family, and Well-Being (WFW) used random-digit dialing to ensure the inclusion of unlisted numbers, calling each selected number up to ten times (Waksberg 1978). Within each household the person eighteen years old or older with the most recent birthday was selected as respondent. (This randomly selects a household respondent [O'Rourke & Blair 1983].) Up to ten attempts were made to speak with the selected respondent and complete the interview. Eighty-two percent of contacted households produced completed interviews, yielding a total of 2,031 respondents ranging in age from 18 to 90.

The National Survey of Personal Health Practices and Consequences (HP) was taken in 1979 with reinterviews in 1980. The sampling began with a random selection of telephone exchanges, followed by a random selection of telephone households in proportion to the number of households served by each exchange, followed by the random selection of an eligible respondent from each household. The sample was limited to adults older than 17 and younger than 65 at the time of the first interview. Eighty-one percent of the selected phone numbers that were working, residential, and owned by a household with at least one eligible respondent produced a complete interview in wave 1. A total of 3,025 respondents were interviewed the first year and 2,436 were reinterviewed a year later.

MEASURES

The two surveys provide roughly comparable measures, as described below.

Impairment

Our analyses measure health in terms of impaired physical functioning using indexes of standard content described below. Functional impairments such as difficulty grasping, seeing, or using stairs correlate with other measures of health such as subjective health, work disability, dependence on others, diagnosed medical conditions (like heart disease or diabetes), and inability to perform common daily activities (like shopping or cooking) (Johnson & Wolinsky 1993; Nagi 1976; Waldron & Jacobs 1988). Physical impairment detracts from the subjective quality of life, interferes with many types of employment, and lowers chances for survival. As a measure of health, impairment provides certain advantages compared to others: it is less subjective than perceived health; it is less affected by access to medical care than counts of diagnosed conditions, physician visits, hospital stays, and the like; it is less episodic than symptoms such as headaches; and it is relevant to a broader population than measures geared to hospitals and nursing homes (McDowell & Newell 1987).

The Work, Family and Well-Being (WFW) index of physical impairment has seven questions asking the respondents to state the amount of difficulty they have with (1) going up and down stairs; (2) kneeling or stooping; (3) lifting or carrying objects less than 10 pounds, like a bag of groceries; (4) using hands or fingers; (5) seeing, even with glasses; (6) hearing; and (7) walking. Those who say they have no difficulty are coded 0; those who say they have some difficulty

are coded 1; and those who say they have a great deal of difficulty are coded 2. The index averages the seven responses. Alpha reliability is .80.

The Health Practices index of physical impairment has five questions asking the respondents to state the amount of difficulty they have with (1) walking; (2) using stairs or inclines; (3) standing or sitting for long periods; (4) using fingers to grasp or handle; (5) lifting or carrying something as heavy as 10 pounds. Those who say they have no difficulty are coded 0; those who say they have some difficulty are coded 1; and those who say they have a great deal of difficulty are coded 2. The index averages the responses to all five questions. The alpha reliability is .84 for the first wave and .82 for the second.

Income

The 1990 WFW survey asked, "During 1989, what was your *total household income,* including income from all members of the household and from all sources, before taxes?" Anyone who did not report an amount was asked, "Could you tell me, was it less than $30,000 or more than $30,000?" If they said it was less, they were asked,"Was it less than $20,000?" The probes continued until the person's income could be placed in one of the following ranges (in thousands): < 10, 10-20, 20-30, 30-40, 40-50, 50-75, 75-100, and > 100. The respective ranges were assigned the following income values (in thousands of dollars): 5, 15, 25, 35, 45, 62, 87, and 100. If someone answered "Don't know" or refused at any point in the probe, they were coded as missing. Of the 2,031 persons in the sample, 1,243 reported an exact amount on the initial question (61.2%), 492 cooperated with the probe and have an approximate value (24.2%), and 296 refused or claimed not to know and have missing values (14.6%).

The regression analyses deflate the 1989 incomes in the 1990 WFW survey to 1978-dollar equivalents for comparison to the 1979 Health Practices survey. To convert, we multiplied income in the 1990 WFW data by the ratio of 1989 consumer price index and 1978 consumer price index (.766/1.380 = .555).

The 1979 Health Practices survey asked, "Please tell me into which of the following groups your family's combined income fell in 1978, before taxes: Less than $5,000, $5,000 to $9,999, $10,000 to $14,999, $15,000 to $24,999, or $25,000 or more?" A year later they were asked the same question about income in 1979. Responses are coded respectively (in thousands of dollars) as 2.5, 7.5, 12.5, 20, or 30. Of those interviewed, 93.0% reported their 1978 income and 95.2% reported their 1979 income. The rest have missing values.

Economic Hardship

In the WFW survey economic hardship is measured as the mean response to the three questions: "During the past twelve months, how often did it happen that you (a) did not have enough money to buy food, clothes, or other things your household needed? (b) did not have enough money to pay for medical care? (c) had trouble paying the bills? Would you say never (coded 0), not very often (1), fairly often (2), or very often (3)?" The hardship index averages the responses to all three questions. Its alpha reliability is .82.

In the 1979-80 Health Practices survey economic hardship is measured by two questions, "Does it ever happen that you do not have enough money to

afford the kind of medical care you or your family should have" (coded no = 0 and yes = 1), and "Please tell me if a serious financial difficulty or problem happened in your life during the past five years" (no = 0, yes = 1). The hardship index is the mean response to the two questions. Reliability is .58 in the first wave and .67 in the second.

Exercise

In the WFW survey the exercise index is the mean of two individual measures: *walking* and *strenuous* exercise. *Walking* is measured as the number of days walked per week. Respondents were asked, "How often do you take a walk? Would you say never (coded 0), once a month or less (.25), about twice a month (.5), about once a week (1), twice a week (2), three times a week (3), more than three times a week (5), or every day (7)?" Strenuous exercise is measured by the question "How often do you do strenuous exercise such as running, basketball, aerobics, tennis, swimming, biking, and so on?" Responses are coded as the number of days per week in the same way as *walking*, except that the highest response category are those who exercise more than three times a week (coded 5). Because of a small correlation between the weekly frequency of strenuous exercise and that of walking, the reliability of the two-item index is only .27.

In the Health Practices survey, *exercise* is measured by seven questions concerning leisure time physical activities: "Please tell me how often you participate in these activities. How often do you (a) go swimming in the summer; (b) take long walks; (c)work on a physically active hobby such as dancing or gardening; (d) go jogging or running; (e) ride a bicycle; (f) do calisthenics or physical exercise; (g) participate in any active sports I haven't already mentioned?" Responses are coded never (1), rarely (2), sometimes (3), often (4). The index is the mean response to the seven questions. A high score on the index indicates higher levels of exercise. The alpha reliability for this index is .74 in both waves.

Education

The 1990 WFW survey asked, "What is the highest grade or year in school that you have completed?" Responses are coded in years up through 16 (for a college degree), with some graduate school experience assigned a score of 17 and a graduate or professional degree assigned a score of 18. The 1979 Health Practices survey asked, "What was the last grade or year of school you completed?" The response categories are none, 1-4 years, 5-6 years, 7-8 years, 9-11 years, 12 years (completed high school or equivalent), 13-15 years (some college or trade school), and 16 or more years (completed college or more). The respective codes are 0, 2.5, 5.5, 7.5, 10, 12, 14, and 16.

Other Social Background

The regressions must be adjusted for sociodemographic variables that might create a spurious association between income and impairment. The candidates include variables with moderate to large effects on both household income and health: age, sex, race, and marital status. Both surveys measure *age* in number of years and define dummy variables contrasting *females* (coded 1) with males

(0), *whites* (1) with nonwhites (0), and persons married or living with someone as *married* (1) with those who are single, divorced, separated, or widowed (0).

ANALYSES

Our analyses fall into three sets. The first set describes the cross-sectional profile of impairment by level of income. It shows whether the slope flattens at high levels of income, shows whether there is a level of income below which the slope is negative and above which it is not, and specifies a functional form that describes the curve. The second set reports cross-sectional regressions that bear on four of the hypotheses. Beginning with a bivariate regression, we progressively add adjustments for social background (precursors of both income and impairment), economic hardship, exercise, and the interaction of education with income. We run the same set of regressions using both data sets. Cross-sectional regressions leave some ambiguity about causal direction. Nevertheless, they provide information that can support or contradict specific hypotheses. Cross-sectional regressions also provide a better test of the social-background hypothesis than can over-time regressions because an ascribed status such as race or sex, or a stable one such as education or marriage, may determine the initial level of income and impairment but not the amount of change in either one net of those initial levels. The third and final set of analyses specifies over-time regressions that allow us to rule out pure selection (health causes income rather than income causing health) and to investigate the possibility of compounding problems (health and income affect each other).

Results

CROSS-SECTIONAL PROFILE

The basic association between income and physical impairment is negative. The profile of the association is consistent with the idea that income reduces impairment by helping to meet basic needs. Figure 2 shows the crude mean impairment scores by $10,000 income groups in the 1990 WFW data. The bold line profiles the mean impairment across levels of income. The dotted lines show the 95% confidence intervals for the means. A one-way analysis of variance finds both the linear trend and the deviation from linearity significant at $p < .001$ ($r = -.209$, $eta = .304$). The profile of means in the graph makes the nonlinearity apparent. Mean levels of impairment drop the most in the step from the lowest category of income to the second lowest — ranges with upper bounds at roughly the 6th percentile and the 20th. The adjacent confidence intervals do not overlap. Mean impairment drops next most in the step from the second category of income to the third, and again the adjacent confidence intervals do not overlap. From that boundary the mean seems to slope down gently through the third, fourth, and fifth categories of income, which have overlapping confidence intervals. Taken together, those categories of income range from the 20th percentile to the 76th. The third largest drop in mean impairment comes at the step from the fifth to the sixth category, and again the adjacent confidence intervals do not overlap. From the top of that category at

about the 83rd percentile to the top of the income distribution at the 100th percentile impairment seems to rise gently but the confidence intervals overlap considerably, meaning that the apparent rise is not statistically significant. Most of it probably reflects the positive association between age and income.

The earlier 1979-80 Health Practices data also show a diminishing negative association between impairment and income. The Health Practices survey's measure of income is crude compared to that in the WFW survey, but the overall pattern remains broadly similar. The steepest drop comes between the two lowest categories of income, which have their upper bounds at the 6th and 18th percentiles. The full bars in Figure 3 represent the mean 1980 impairment. The top part of each bar represents the mean impairment in 1979, and the bottom part represents the average increase over the one-year follow-up. One-way analyses of variance shows that both the linear trend and the deviation from linearity are significant at $p < .001$ in both years ($r = -.167$ and $-.173$ and $eta = .215$ and $.231$ in 1979 and 1980 respectively). The one-year increase in impairment is significantly greater than zero at $p < .001$ for all categories of income, despite the fact that the sample was limited to adults younger than 65. The linear trend in one-year change and its deviation from linearity are not significant in an analysis of variance ($p = .281$ and $.234$ respectively), but the correlation becomes significant after taking the cube root of income, as described below.

Both surveys show the greatest difference in mean levels of physical impairment between the lowest category of income and the next highest one. Both show diminishing steps down in average physical impairment in successively higher categories of income. Both the 1990 cross-section and the changes from 1979 to 1980 suggest a slight but statistically insignificant rebound at high levels of income, possibly because income and impairment both increase with age. Thus, regressions should adjust for age.

The curvilinear relationship between impairment and income can be approximated by transformations that shrink successive intervals, mathematically mimicking the diminishing effects. The transformations that represent diminishing effects also correct income's highly skewed distribution. Figure 2 shows the number of cases in each $10,000 bracket of income in the 1990 WFW data. The number of cases increases progressively up to the fourth bracket and decreases progressively in the next eight. The skewed distribution suggests that income may have diminishing effects at high levels partly because larger and larger increases are required to move up a rank. Because a positive skew can be reduced by taking a logarithm, a square root, or a cube root (Hamilton 1992), taking the logarithm in the 1990 WFW data reverses the skewness from 3.363 to -.885. Taking the square root brings it down to .668 and taking the cube root brings it down to .057. The standard error of the skewness is .054 regardless of the transformation, so the t values are 62.278, -16.389, 12.741, and .688 respectively. Thus the skewness of income in its cube-root form is not significant ($t < 1.960$). The cube-root transformation of income also makes its bivariate correlation with change in impairment become statistically significant. The transformation increases the t value of the correlation from -1.273 to -1.804, which lowers the one-tailed p value from .102 to .036 (or from .203 to .071 two-

tailed). The regressions that follow use the cube-root of income in thousands of dollars ($\$k^{1/3}$).

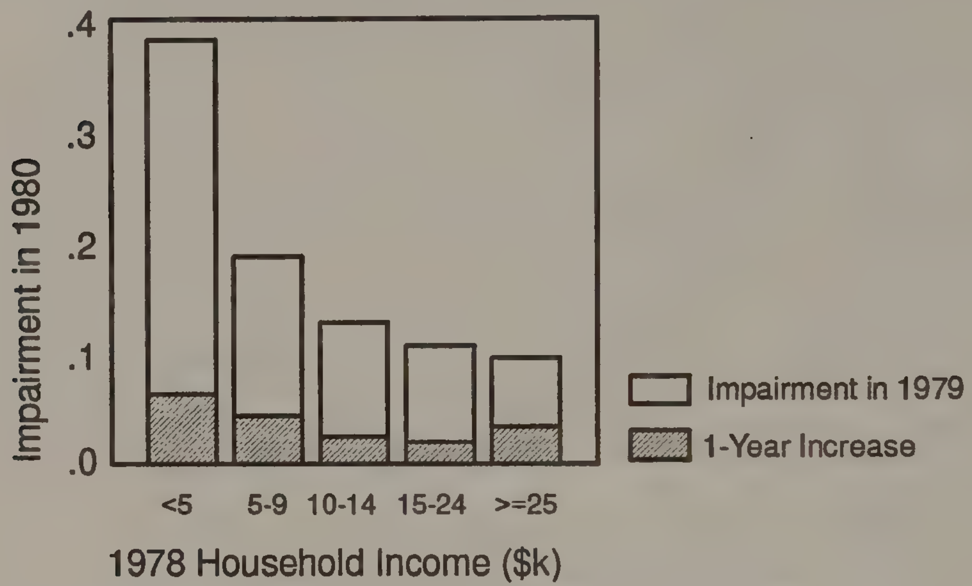
CROSS-SECTIONAL REGRESSIONS

The cross-sectional regressions provide information relevant to the hypotheses of basic needs, resource substitution, status lifestyle, and social background. Table 1 shows the cross-sectional regressions for the 1990 WFW data, and Table 2 shows parallel cross-sectional regressions in the 1979 Health Practices data.

Basic Needs

A substantial fraction of income's estimated total effect on impairment appears attributable to economic hardship. In the terms of causal analysis, the coefficient of income adjusted for its precursors represents its "total causal effect" in the model (Davis 1985). Step 2 in Tables 1 and 2 shows the regression coefficient with adjustment for social background and step 3 adds adjustment for economic hardship. The adjustment for economic hardship reduces income's coefficient by an additional 32.7% in the WFW data ([.052 - .035]/.052 = .327) and by 50.0% in the Health Practices data ([.094 - .047]/.094 = .500). The reduction is 1.545

FIGURE 3: Impairment by Income, 1979 and 1980 Health Practices Data



standard errors in the WFW data and by 3.615 standard errors in the Health Practices data. Taken together these results seem consistent with the argument that economic hardship accounts for part of the association between low income and physical impairment.

Resource Substitution

Both sets of regressions show that education significantly reduces the relationship between income and impairment. The interaction term is significant and positive in step 5 of Tables 1 and 2. In each case the coefficient of income indicates that it has a significant negative effect on impairment at the sample's mean level of education. (Education is measured as a deviation from its mean, so the coefficient of income in the interaction model represents its effect at the sample's mean level of education [Aiken & West 1991]). The positive coefficient for the interaction of income by education indicates that income's negative effect gets smaller as education rises. The left panel of Figure 4 illustrates the prediction for 10, 12, and 14 years of education in the 1990 WFW data, with the 1989 dollars converted to 1978 equivalents (for comparison to the Health Practices cross-sectional and over-time results). The cross-sectional regressions based on the 1979 Health Practices data would show a similar pattern. Both data sets yield a significant interaction between income and education. The negative association between income and impairment becomes stronger at lower levels of education. Thus, consistent with the alternative-resource hypothesis, the combination of low education with low income sharpens the association between low income and physical impairment.

[a] The cross-sectional model on the left uses the 1990 WFW data. The over-time model on the right uses the 1979-80 Health Practices data.

Status Lifestyle

Habits of exercise associated with higher income appear to account for little or none of the negative cross-sectional association between income and impairment. Exercise has the predicted negative coefficient in both samples (although, given the cross-sectional nature of the data, infrequent exercise might *result* from impairment). Nevertheless, adjustment for exercise changes income's coefficient very little, as shown by comparison of steps 3 and 4 in Tables 1 and 2. The biggest change is in the Health Practices data (which has a more reliable exercise index), where the additional adjustment of step 4 reduces income's coefficient by 1.230 standard errors — well within the 95-percent confidence range of the coefficient in step 3. Notably, adding the adjustment for exercise in the Health Practices data reduces *education's* coefficient by 32%, or 2.000 standard errors.

Social Background

Adjustment for social background reduces income's coefficient by 59.1% in the WFW data ([.127-.052]/.127 = .591) and by 33.3% in the Health Practices data ([.141-.094]/.141 = .333), as shown by comparison of steps 1 and 2 in Tables 1 and 2. Thus, the adjustment reduces the coefficient by 6.8 standard errors in the WFW data ([.127-.052]/.011 = 6.8) and by 4.3 standard errors in the Health

† $p < .10$ (two-tailed) * $p < .05$ ** $p < .01$ *** $p < .001$

Practices data ([.141-.094]/.011 = 4.3). These ratios are considerably larger than the 1.96 standard errors that correspond to a probability value of .05 in a two-tailed t test. Thus, social background appears to account for a substantial and significant part of the total association between income and impairment. Education and sex appear to be the most important background contributors to the correlation. Education has a larger standardized direct effect than any background measure other than age. Age acts as a suppressor of income's negative correlation with impairment, because income rises over most of the range of ages in the sample and impairment also rises with age. Thus, adjusting for age actually increases income's coefficient compared to what it would be otherwise. Sex also has a significant direct effect in both samples, with women more impaired than men. Race and marriage have unstable effects, with each being significant in one sample but not the other. However, the signs of their coefficients remain consistent with the social background hypothesis, with whites and married people being less impaired.

REGRESSIONS OF CHANGE OVER TIME

The regressions of change over time serve three main purposes: they allow us to rule out pure selection as an alternative to the basic-needs hypothesis; they allow us to rule out a selection alternative to the resource-substitution hypothesis; and they provide evidence of selection effects that might contribute to the compounding of problems. We detail these and related points below. The over-time regressions all follow the same basic form, described in equation 1:

$$\Delta Y = b_0 + b_1 Y_{t1} + \sum_{i=2}^{k} b_i X_i + u_{\Delta Y} \tag{1}$$

In equation 1, b_i represents the effect of X_i on change in Y adjusting for its initial state at time one (Y_{t1}). The coefficient b_1 represents the instability of the outcome over the one-year period. Given that $\Delta Y = Y_{t2} - Y_{t1}$, equation 1 is algebraically equivalent to equation 2, where $1 - b_1$ represents the stability of the outcome:

$$Y_{t2} = b_0 + (1-b_1) Y_{t1} + \sum_{i=2}^{k} b_i X_i + u_{Y_{t2}} \tag{2}$$

Thus, the regression coefficients may be interpreted as effects on change net of initial state or as effects on outcome net of initial state. Only the coefficient of Y_{t1} differs in the two versions, representing instability in equation 1 and stability (1 minus instability) in equation 2.

Basic Needs

The previous cross-sectional results clearly show a negative association between income and health. The profile of the association seems consistent with the basic needs hypothesis. However, the association could result entirely from the impact of impairment on income. If physical impairment interferes with the ability to earn income, then some part of the cross-sectional association results from the social processes that move impaired persons downward in the income distribution. It is possible that *all* the cross-sectional association results from

selection and *none* of it from the health consequences of failing to meet basic needs. One way to rule out this alternative is to show that income predicts the rate and direction of subsequent change in impairment adjusting for initial level of impairment. The first column of Table 3 shows that regression, adjusting for social background and the initial levels of hardship and exercise.

Table 3 shows a significant negative effect of income on change in impairment. Thus, higher income predicts a lower rate of increase in impairment. Physical impairment tends to rise over time as people get older. The mean change in impairment is .032 on an initial mean level of .119, even though the Health Practices survey followed adults younger than 65 for only one year. The aggregate increase is significantly greater than zero at $p < .001$ ($t = 6.591$). The regression coefficient associated with the cube root of income is -.033, so a unit increase in the cube-root of income above its mean reduces the predicted change to zero. That level of income is about $42,600 in 1978 dollars, or $76,800 in 1990 dollars (the mean cube-root income is 2.494, which corresponds to 15.414 thousands; a cube-root income of 3.494 corresponds to 42.655 thousands; 1990 dollars are 1.8 times their 1978 equivalents). This theoretical income at which the rise of impairment vanishes is above the level of the code for the highest income category in the Health Practices data (30,000). Nevertheless, it is reasonable to infer that the expected rise of impairment tends to vanish at higher levels of income for adult Americans younger than 65.

The effect of economic hardship also tends to support the basic-needs hypothesis. Impairment rises more rapidly for those reporting earlier economic hardship. Of course, one indicator of economic hardship is not having enough money to pay for medical care, which could be a measure of health problems as much as of economic difficulties. The other indicator of economic hardship in the Health Practices data is any serious financial difficulty or problem over the five years preceding the initial interview. In a subsidiary regression analysis not shown in Table 3 we allowed forward stepwise regression to choose among the report of serious general financial difficulty, the report of difficulty paying for medical care, and the index averaging the two (probability for inclusion = .05, two-tailed). The procedure selected the index alone, indicating roughly equal effects of the two aspects of hardship on the change in impairment.

The direct effects of income and economic hardship on change in impairment support the basic-needs hypothesis. However, a progressive adjustment of income's effect on change in impairment does not show that hardship accounts for a large or significant fraction of income's total effect. The regression in the first column of Table 3 corresponds to the fully adjusted step 5 in Tables 1 and 2. A progressive adjustment of income's effect over time that are parallel to steps 1 through 4 in Tables 1 and 2 shows little change as adjustments are added. The regression coefficient is -.050 adjusting for initial impairment alone, -.044 adding adjustment for social background, -.038 adding adjustment for economic hardship, and -.034 adding adjustment for exercise. As in the cross-sectional analyses, the adjustments for social background and economic hardship reduced the size of income's coefficient the most. However, the changes are small compared to the coefficient's standard error of .011 — no larger than .545 standard errors. Thus, the changes with adjustment are all well within the 95% confidence limits of the original coefficient.

Resource Substitution

The cross-sectional results show that the strength of the negative association between impairment and income diminishes at higher levels of education. Selection forces could plausibly account for such a pattern if impairment reduces income less among those with higher education. For example, the incomes of manual laborers might be undermined by physical impairment far more than, say, the incomes of executives. Manual laborers tend to have high school education rather than college degrees. Thus, the stronger negative correlation between income and impairment could reflect a stronger effect of impairment on income at low levels of education, rather than a stronger effect of income on impairment. Two findings rule out this alternative interpretation. First, we find the same interaction between income and education as predictors of *change* in impairment: the effect of low income on change in impairment diminishes at higher levels of education, as shown in the right panel of Figure 4. Second, we find no indication of a significant interaction between education and impairment in *any* of the four over-time regressions, including the one predicting change in income. The p value for the education-by-impairment interaction term is .990 and .438 when the term is added to the equations predicting change in income and in economic hardship respectively.

Resource substitution also appears to occur with regard to economic hardship. Table 3 shows that education and income interact in their estimated effect on change in economic hardship. Higher education and income each predict relative declines in economic hardship, but less so in combination than implied by their separate effects. Put another way, low income tends to increase economic hardship, but less so the higher one's education.

Compounding Problems

Taken together, the regressions in Table 3 imply the compounding of problems over time. Physical impairment, income, and economic hardship significantly affect subsequent changes in each other. Impairment and exercise also significantly affect subsequent changes in each other. The signs of the coefficients all imply that changes tend to amplify rather than dampen. For example, impairment reduces income and exercise and increases economic hardship, all of which increases subsequent impairment. The result is a web of reinforcing effects — particularly among impairment, income, and economic hardship.

It is difficult to say exactly how much impact these self-reinforcing effects might have over a long period of time. Clearly, over a one-year period the indirect effect of one outcome on itself through the others cannot be large. To get a rough sense of the size of the one-year magnification we estimated a two-stage least-squares model of reciprocal effects between income and impairment. We used each outcome's initial value in 1979 as an instrument for its 1980 value in a standard reciprocal-effect model. The resulting coefficients imply that the reciprocal effect magnifies stochastic shocks by about .50 percent within the one-year period (that is, $[1 + b_{yx}\ b_{xy}]^{-1} = 1.005$). The annual rate seems small, but compounded over the 40 years of adulthood between ages 20 and 60 it would become a 22% enlargement of the initial effect ($1.005^{40} = 1.22$). For 10, 20, and 30

years of compounding the enlargement would be 5%, 10%, and 16% respectively.

Taken together, the over-time regressions indicate that physical and economic problems compound over time. The effect appears to be relatively small over a short period of time, but it could have substantial long-term consequences.

Status Lifestyle

The over-time regressions show that greater income predicts more positive changes in exercise. Average amounts of exercise declined significantly over the one-year period ($\Delta\bar{Y} = -.068$, $t = -3.237$, $p < .001$). The regression implies that the predicted decline in exercise is zero if income is $23,639 in 1978 dollars (or $42,552 in 1990 dollars) and all the other variables are at the sample mean. Exercise in turn significantly reduces the expected rise in impairment.

In regard to exercise, income appears to operate as a determinant of lifestyle rather than as an economic resource per se. Economic hardship has no significant effect on changes in exercise, but education has a positive effect as does income. Although exercise increases with social status, the over-time regressions give no indication that exercise helps people to rise in status, except to the extent that exercise forestalls impairment. Exercise has no significant net effect on changes in income or on changes in economic hardship controlling for impairment.

Social Background

Given the adjustment for baseline impairment, income, hardship, and exercise, social background has comparatively little effect on subsequent changes in the four outcomes. Not surprisingly, age has the biggest effects of the background variables, reflecting its role as an index of position in the life course. Older age accelerates the rise of impairment, the decline of exercise, and the decline of economic hardship, and slows the rise of income. Education also has effects on changes in all four outcomes, often modifying the effect of income. As noted in an earlier section, education and income operate as partial substitutes for each other in their effects on change in impairment and in hardship. Education also reduces the instability in income (or, alternatively, increases its stability), as indicated by a positive interaction with initial income in its effect on changes in income. Education also tends to slow the general decline in exercise over time. Table 3 shows only two other effects of background variables: physical impairment rises faster for women than for men, and household income rises faster for married people than for others.

Discussion

Our results confirm the sharp concentration of physical impairment near the bottom of the income distribution. By far the largest differences in physical impairment occur between the lowest and the next-to-lowest categories of income. Well over half the total decline in mean levels of impairment occurs between the bottom of the income distribution and the 6th percentile. Most of

the rest occurs between there and the 20th percentile. A number of results support the inference that the concentration comes in part from the deleterious effect of low income on health: a large fraction of the cross-sectional association survives adjustment for precursors that affect both income and impairment; a substantial fraction of the cross-sectional association vanishes with adjustment for economic hardship; lower income predicts steeper increases in physical impairment over time; and lower income predicts increased economic hardship and decreased frequency of exercise, both of which in turn predict sharper increases in physical impairment over time.

Basic Needs

Several findings suggest that the failure to meet basic physical needs accounts for part of low income's effect on impairment. These findings include the sharp concentration of impairment toward the bottom of the income distribution, the diminishing slope at progressively higher levels of income, the reduction of income's cross-sectional effect with adjustment for economic hardship, and the effects of income and hardship on change in impairment over time. Clearly, income reduces physical impairment in part because it helps people meet their basic physical needs for food, clothing, shelter, and care. Those needs appear to be met for most Americans at around the 20th percentile of household income — or about $20,000 a year in 1989 dollars. Beyond that critical point physical impairment declines relatively little at progressively higher levels of income.

Meeting basic needs partly explains the profile of impairment by level of income, but not entirely. Several other factors contribute to the pattern.

Resource Substitution

Education has two effects that combine to steepen the impairment slope toward the bottom of the income distribution and flatten it toward the top: education increases the level of household income and it decreases the effect of income on impairment. Income decreases impairment more for people with lower education — the very people concentrated toward the bottom of income's distribution. Income decreases impairment less for people with higher education — the very people concentrated toward the top of income's distribution. As a result, any given difference in income produces a greater effect on impairment toward the bottom of the socioeconomic scale than toward the top. Education reduces the need for money in the sense that it reduces the level of physical impairment, the rate of increase in physical impairment over time, the effect of income on the level of impairment, the effect of income on the rate of increase in impairment, and the effect of income on the rate of change in economic hardship. In part, the effect of greater income on impairment diminishes because education increases the typical level of household income while simultaneously diminishing the need for greater income.

Compounding Problems

The compounding of economic and health problems contributes to the increasing gradient of impairment at lower and lower levels of income. Income, economic hardship, impairment, and exercise form a web of mutually reinforcing effects that concentrate physical and economic problems together over time. Physical impairment slows or reverses the rise of income and the decline of economic hardship otherwise expected between the ages of 18 and 65. Lower income and greater economic hardship accelerate the rise of impairment. Similarly, impairment reduces the frequency of exercise, and lack of exercise speeds the rate of increase in impairment. The annual rate at which problems compound may be low — less than 1% by our rough estimate — but projected over decades of adulthood the effect could become substantial.

Status Lifestyle

Exercise's impact as an aspect of status lifestyle seems uncertain. On one hand the results clearly indicate that exercise forms part of a high-status lifestyle. Education and income both slow or reverse the decline of exercise over time. The effect appears to reflect lifestyle more than resources, because economic hardship has no effect on changes in exercise. Clearly, exercise predicts a slower rate of increase in impairment over time. On the other hand, adjusting for exercise in the cross-sectional analyses does not reduce the association between income and impairment. Furthermore, habitual exercise may come out of a high-status culture but it does not open doors to a high-status position. In the over-time analyses exercise does not improve income or reduce economic hardship, except indirectly by suppressing the rise of impairment. Outside its role in the web of compounding problems, exercise probably does not account for the concentration of impairment with low income.

Social Background

Shared social precursors account for 33.3% to 59.1% of the cross-sectional correlation between income and physical impairment. Education and sex play the biggest and clearest part, but race and marriage may contribute to the correlation too. Women have lower income and greater impairment than men, and women's impairment rises more rapidly over time. However, education operates as the single most important element of social background. Given the effects of education discussed in previous sections, education's background centrality comes as no surprise. The cross-sectional results attribute a remarkably large fraction of the association between income and impairment to fixed or highly stable social attributes — particularly education.

CONCLUSION

Why does income's incremental effect on physical impairment seem to diminish? Perhaps the question should be put the other way around. Why does the level of physical impairment rise ever more sharply toward the bottom of the income distribution? Looking at the results overall, a picture emerges. Education stabilizes by early adulthood, but its effects remain in force and

compound each other over decades, concentrating physical impairment and low income together. Throughout adulthood low education reduces income while sharpening the impact of low income on economic hardship and physical impairment. The effects compound over time, with impairment giving rise to greater hardship while further undermining income. Over the decades of adulthood each consequence of education accelerates changes in the others. By slowing the rise of income and speeding the rise of impairment, low education concentrates poverty and disability together.

If unmet needs and economic hardships produce physical impairments, then meeting the needs and reducing the hardships may sustain and improve physical functioning. In terms of impairment, the sharpest needs for additional income are limited to a minority of the population — no more than 20%. The amount of additional income needed appears to be in the range of $10,000 each. Suppose we could tax the rest of Americans to raise the money. How high would the tax be? There are four Americans above the critical level for every one below, so each one above would have to pay $2,500 in new taxes. The hard reality is that we in the upper 80% probably would not agree to pay so great a tax, even if we could be certain that it would eliminate the impairment of the needy. Education may provide the lever that can move this stone; it may lift people above the most serious needs by helping them to get higher income and to use their income more effectively.

Contextual Influences on Young Men's Transition to First Marriage*

KIM M. LLOYD, *State University of New York at Albany*
SCOTT J. SOUTH, *State University of New York at Albany*

Abstract

Competing theories of marriage formation are evaluated by merging several contextual variables, primarily marriage market characteristics from the 1980 census, with men's marital histories observed between 1979 and 1984 in the National Longitudinal Survey of Youth. Discrete-time event history models reveal that, net of conventional individual-level predictors, a shortage of prospective partners in the local marriage market impedes white men's transition to first marriage. Women's aggregate economic independence, measured in terms of the proportion of females in the local marriage market who are employed and in terms of the size of average AFDC payments, also diminishes men's marriage propensities. Although earnings and home ownership facilitate men's marital transitions, racial differences in socioeconomic and marriage market characteristics account for relatively little of the substantial racial difference in marriage rates.

Patterns of family formation in the U.S. are undergoing substantial change. The latter half of this century has witnessed an overall retreat from marriage, with both the age at first marriage and the number of persons choosing to forgo marriage altogether increasing dramatically (Cherlin 1992). Although pervasive declines have occurred among all races, the retreat from marriage has been especially pronounced among African Americans. For example, in 1970 roughly the same proportion of black and white males had married by the age of 24 — 44% and 45%, respectively. However, by 1990, the proportion of black males who had married by age 24 had plummeted to 13%, compared to 22% of white males (U.S. Bureau of the Census 1991, 1993). Similar declines in marriage are found among white and African American females (Cherlin 1992).

Past research has not yet clearly identified whether increasing age at first marriage and increasing nonmarriage are caused by men's, women's, or both sexes' reluctance to form marital unions (South 1993). While the mutual nature of any marital decision is both obvious and straightforward, most discussions

and empirical investigations of racial differentials and recent declines in marriage emphasize changes in *women's* perceptions and behaviors (e.g., Becker 1981; Espenshade 1985; Marini 1978; Schoen & Owens 1992). For example, ecological observations of marriage incidence (South & Lloyd 1992b) and prevalence (Preston & Richards 1975), individual-level longitudinal analyses of marital timing (Waite & Spitze 1981), and even contextual analyses of marital transitions (Lichter et al. 1992; McLaughlin, Lichter & Johnson 1993; Oropesa, Lichter & Anderson 1994) have, with few exceptions (Goldscheider & Waite 1986; Teachman, Polonko & Leigh 1987), focused exclusively on women's marital behaviors, thereby implicitly assuming that men's nuptial aspirations are less central to recent declines.

The present analysis makes three contributions to research in this area. First, by examining the determinants of men's marital transitions we provide a needed balance to previous studies that emphasize women's marital behavior. Second, we examine directly, and for the first time, the impact of marriage market characteristics and other contextual variables on men's transitions to first marriage while simultaneously controlling for conventional, individual-level predictors. This strategy allows us to evaluate competing models of the effects of the quantity and "quality" of females in men's marriage markets on their transition to first marriage. And third, we examine the extent to which racial differences in men's marital timing can be attributed to racial differences in demographic and socioeconomic characteristics, as well as to differences in marriage markets.

Factors Influencing Men's Transition to First Marriage

Marriage is one of the most important transitions that young men (and women) make as they enter adulthood (Goldscheider & Waite 1986). Marriage provides a clear indication of the passage from childhood to adulthood and is therefore a pivotal point in the life course. Theoretical explanations of marital transitions focus on both the marriage market conditions under which individuals search for a suitable spouse and individuals' own characteristics that make them either a desirable or an undesirable marriage partner.

MARRIAGE MARKET CHARACTERISTICS

Although few analyses have directly examined the impact of male marriage opportunities on men's marital behavior, theories of marriage timing are not completely silent on this issue. Theories of both marital search behavior and imbalanced sex ratios stress the numerical availability of potential partners but predict very different marital dynamics for men. Discussions of marital search behavior suggest that several aspects of the marriage market influence marriage propensities. Foremost among these is the numerical availability of potential partners. Local marriage markets that are characterized by discontinuity between the supply and demand for conjugal mates lead some prospective spouses either to remain unmarried or to delay the transition to marriage (Becker 1981; Oppenheimer 1988). It is important to note that theories of marital search behavior do not differentiate between males and females who face

unfavorable marriage market conditions. Therefore, a deficit in the quantity of potential wives should depress the first marriage transitions of males, just as a deficit of desirable potential husbands inhibits women's marriage (Lichter, LeClere & McLaughlin 1991; Lichter et al. 1992; South & Lloyd 1992b).

In contrast, theories of imbalanced sex ratios assert that when men are subjected to unfavorable marriage opportunities — that is, when there are more marriageable males than females in the local marriage market — men are *more* likely to marry (Guttentag & Secord 1983). Under these circumstances, women are in short supply and therefore men are motivated to commit to marriage in order to maintain a relationship with an opposite sex partner. Conversely, when men enjoy a favorable ratio of potential mates — that is, when there are more marriageable females than males in the local marriage market — men will be *less* likely to marry. Instead, it is argued, when there is an abundant supply of women, men utilize the increased number of female alternatives to avert or delay marriage (Fossett & Kiecolt 1990, 1993; Guttentag & Secord 1983). The relative surfeit of women available to men makes it unnecessary for men to commit to a single partner.

An interesting paradox exists when attempting to assess the relative merits of these competing theories. The overwhelming majority of research done on marital transitions, and virtually all studies of marriage market effects, have examined only women's marital timing. However, theories of marital search behavior and imbalanced sex ratios predict identical behaviors for *women* under similar marriage market conditions, and thus these studies cannot adjudicate between these competing theories. Both theories predict that women encountering numerous men in the local marriage market will have high marriage rates. Empirical investigations of women's marital behavior demonstrate that female marriage rates *are* positively related to the numerical supply of potential spouses, i.e., single men (Lichter et al. 1992; McLaughlin, Lichter & Johnson 1993; South & Lloyd 1992b). But these theoretical perspectives do predict a different relationship between mate availability and men's marriage propensities. Because there have been few empirical investigations of the impact of marriage opportunities and men's transition to marriage, however, it is not certain whether a surfeit of eligible women increases men's propensity to marry, as the marital search model would predict, or decreases the probability that men will form conjugal unions, as theories of imbalanced sex ratios assume.[1] This apparent conflict between competing theories justifies a focus on the influence of marriage market characteristics on men's marital transitions (Lichter et al. 1992).

Empirical investigations of *women's* marital timing demonstrate the importance of considering the "quality" of available mates, as well as their sheer quantity (Fossett & Kiecolt 1991; Lichter et al. 1992; South & Lloyd 1992b; Wilson 1987). Of particular importance for hastening *women's* entry into marriage is the employment and educational status of potential husbands. There are also reasons to anticipate that the characteristics of potential wives in the local marriage market will affect men's marital transitions, although contradictory expectations can be derived from the literature. On the one hand, South (1991) demonstrates that recent cohorts of unmarried men express a verbal preference for employed over unemployed wives. Mare and Winship (1991) find

that African American women who have good labor market prospects, as indicated by a high level of educational attainment and high weekly earnings, are more attractive to potential husbands. Thus, greater female labor force participation and higher levels of female educational attainment may increase *men's* gains from marriage, making employed and highly educated women more attractive marital prospects. This line of argument implies that male marriage propensities will be higher in marriage markets that contain a higher proportion of women who are employed or who have relatively high levels of completed schooling.

On the other hand, research focusing on *female* marriage transitions stresses the opposite dynamic by focusing on the role of women's economic independence as a deterrent to marriage formation. Theoretically, women will be less inclined to marry if they have attractive alternatives to the traditional role of wife and mother (Goldscheider & Waite 1986; Preston & Richards 1975; Teachman, Polonko & Leigh 1987; cf. Lichter et al. 1992). For example, women who are active in the labor force have greater financial security and therefore fewer economic incentives to marry. Additional support for this view is provided from theories of marital search behavior that suggest that favorable labor market status on the part of females should also depress male marriage rates because employment and education extend a woman's marital search process while simultaneously raising the "reservation quality" of her potential partner (Oppenheimer 1988). Presumably, the end result is that women who are employed or obtain high levels of education will be less likely to marry or will postpone their first marriage transitions.[2] If this is the case, areas with a high proportion of employed females, relative to areas with low levels of female labor force participation, should have lower rates of male marriage. Work by Fossett and Kiecolt (1993) support this position. They find an inverse relationship between black women's aggregate socioeconomic status and employment rate and the percentage of black men who are married across U.S. metropolitan areas. High levels of women's educational attainment should have a similar effect by increasing women's long-term labor market prospects, which thus reduces their anticipated gains from early marriage.

Three other characteristics of the local marriage market — the proportion of females enrolled in school full-time, average size of Aid to Families with Dependent Children (AFDC) payments, and population size — are hypothesized to diminish the probability that a man will marry. Women who are enrolled in school are less active in the marriage market primarily because marriage tends to threaten school completion. Past research consistently demonstrates that school enrollment inhibits marriage formation among both men and women (Goldscheider & Waite 1986; Teachman, Polonko & Leigh 1987). Second, discussions of declining marriage rates often identify the facilitating nature of welfare programs, asserting that they provide females with economic alternatives to male partnerships (Becker 1981; Murray 1984). Therefore, AFDC payments may be an important factor in establishing women's economic independence from traditional family formation. Consistent with this hypothesis is Fossett and Kiecolt's (1993) finding of an inverse effect of AFDC payments on black men's aggregate marriage prevalence across U.S. metropolitan areas. As does the proportion of women in the local marriage market who are currently

employed, who have a high level of education, or who are enrolled in school, AFDC payments serve as an explanatory variable that simultaneously reflects the probability that a male respondent will encounter an attractive and willing marriage partner and the degree to which women, in the aggregate, experience attractive alternatives to marriage. Finally, past studies suggest that urban community norms place less emphasis on traditional family values than do their rural counterparts, resulting in lower probabilities of marriage in densely populated areas (McLaughlin, Lichter & Johnson 1993; Teachman, Polonko & Leigh 1987).

MEN'S INDIVIDUAL-LEVEL CHARACTERISTICS

Prior research suggests that the most important individual-level characteristics facilitating men's transition to marriage are economic status, educational attainment, family background, and value orientation. Given men's traditional role as the family's primary financial provider, past analyses emphasize men's economic circumstances — specifically their labor market participation, job stability, and earnings — as pivotal determinants of marriage (Lerman 1989; Mare & Winship 1991; Oppenheimer, Kalmijn & Lew 1993; Wilson 1987). Economic characteristics are hypothesized to affect not only men's own current marital ambitions but also their attractiveness to potential wives (Oppenheimer, Kalmijn & Lew 1993; Wilson 1987). Men who establish a stable employment history and who earn high income are capable of providing and sustaining an independent household for themselves and their families. These attributes make men more attractive marriage prospects.

Other indicators of men's current and future wealth should also positively influence their marriage propensities. One signal of current financial stability is home ownership, while high levels of educational attainment may reflect future labor market potential and provide clues to long-term economic success (Oppenheimer 1988). Men who own their own homes and have high levels of educational attainment should therefore be more confident that they can provide for a family if they choose to marry. Furthermore, because of their increased socioeconomic status, these men should also find it easier to locate a willing marriage partner (Oppenheimer, Kalmijn & Lew 1993). School enrollment should negatively affect the probability of marriage for several reasons. Past research finds that, as with women, academic involvement inhibits marriage formation primarily because marriage tends to threaten school completion, which in turn may jeopardize a man's future career trajectory (Oppenheimer, Kalmijn & Lew 1993). The financial and time constraints of education probably operate to produce additional delays to marriage (Teachman, Polonko & Leigh 1987).

In addition to economic and educational characteristics, men's family background and value orientation also influence marital timing. Prior discussions of family formation suggest that individuals raised in disrupted family households or with single parents are more likely to delay first marriage (Avery, Goldscheider & Speare 1992), although contrary evidence can be found (Axinn & Thornton 1992; Goldscheider & Waite 1986). Finally, prior research also suggests that there are regional differences in family formation, with

southerners placing a greater emphasis on marriage and the family than do individuals residing in other regions of the country (Goldscheider & Waite 1986).

RACIAL DIFFERENCES IN MEN'S TRANSITION TO FIRST MARRIAGE

While numerous studies have explored levels of, and possible reasons for, the substantial difference in marriage rates between black and white females, the equally pronounced racial difference in men's marital timing has received comparatively little attention.[3] Explanations for the racial difference in female marriage rates have tended to emphasize the relative shortage of desirable black men to serve as husbands for black women (Lichter, LeClere & McLaughlin 1991; Lichter et al. 1992; South & Lloyd 1992b; Spanier & Glick 1980; Wilson 1987; cf. Schoen & Kluegel 1988). It seems unlikely, however, that racial differences in men's propensity to marry could be explained by racial differences in marriage market characteristics. Differences in mate availability between whites and African Americans imply that black men, relative to their white counterparts, enjoy a relative abundance of potential partners; if marital search theory is correct, this should lead to higher marriage rates for black than for white men.

It is possible, however, that racial differences in social and economic characteristics could account for some of the difference in the marriage rates of black and white men. Given the racial gap in such dimensions of socioeconomic status as income, employment, and home ownership, together with the tendency for these variables to increase men's propensity to marry, it is conceivable that some of the racial difference in men's marriage rates could be attributed to differences in these endowments. This view is consistent with Wilson's (1987; Wilson & Neckerman 1986) argument that African Americans' retreat from marriage is largely a consequence of black men's deteriorating labor market position. To examine this issue, we analyze the racial difference in men's timing of marriage both with and without controlling for an array of social and economic characteristics.

Data and Methods

The data for this study come from three sources: The National Longitudinal Survey of Youth (NLSY), the PUMS-D file of the 1980 census, and aggregate county-level data from the *U.S. County and City Data Book* (U.S. Bureau of the Census 1983). The NLSY is a national probability sample of 12,686 non-institutionalized individuals (of whom 6,403 are male), 14 to 22 years old at the time of their initial interview in January 1979. Respondents have been interviewed annually since then, although, for reasons discussed below, the present analysis will be confined to the 1979 through 1984 calendar years. The NLSY has many advantages over competing data sets for investigating young men's transition to marriage. First, the retention rate of the NLSY is high, with more than 90% of respondents remaining in the sample through 1984. Second, the NLSY contains extensive and detailed information on individual marital histories, labor market experiences, and socioeconomic characteristics. Third, the

survey covers the age categories in which most first marriages take place, i.e., 18 through 27. The primary advantage to using the NLSY to examine males' marital transitions, however, is the supplementary geocode files that identify the state and county in which each respondent resides at each annual interview, thereby allowing aggregated census data to be merged with each respondent's individual record.

This analysis restricts the NLSY sample in the following ways. First, following other recent analyses of marital transitions, we exclude individuals who married before age 18 (cf. Lichter et al. 1992; Teachman, Polonko & Leigh 1987). Marriages occurring to males below the age of 18 are quite rare and generally considered nonnormative. Moreover, data on many labor force and human capital characteristics are unavailable for males younger than age 18. Second, we focus on the marital experiences of non-Hispanic whites (hereafter referred to simply as whites) and African Americans. Hispanics display high rates of exogamy, marrying both non-Hispanic whites and African Americans at relatively high frequencies, thus making it difficult to delineate clearly their field of potential mates (Bean & Tienda 1987; Oropesa, Lichter & Anderson 1994). Third, in order to match geocode data from each annual interview, we include only respondents who are eligible for their first marriage between 1979 and 1984. Individuals who were already married before the initial 1979 interview are excluded from the analysis because we lack geocode information on the marriage market in which these marriages were initiated. Marriages that occurred after 1984 are also excluded because of the decreasing temporal accuracy of 1980 census data as measures of post-1980 marriage market conditions (Lichter et al. 1992). And fourth, because so few of the respondents in the early waves of the NLSY experience a second marriage, we focus solely on first marriage transitions. These selection criteria result in an effective sample of 3,907 young men — 2,712 non-Hispanic whites and 1,195 blacks.

DEFINING MEN'S MARRIAGE MARKETS

Most analyses exploring the effects of mate availability on family formation processes recognize that marriage markets are geographically circumscribed. Men (as well as women) search for, and select, marital partners from within local areas. Past research, however, is equivocal on what level of geography is the most appropriate, with various studies utilizing Metropolitan Statistical Areas (South & Lloyd 1992a; White 1981), urban areas (White 1979), counties (Fossett & Kiecolt 1990), and states (Schoen & Kluegel 1988; South & Lloyd 1992b). Following other recent analyses of marriage market effects (Lichter et al. 1992; McLaughlin, Lichter & Johnson 1993), we use data from the 1% PUMS-D file of the 1980 census (Tolbert & Killian 1987) to calculate mate availability measures across the 382 U.S. Labor Market Areas (LMAs). As others have noted (Lichter et al. 1992, South & Lloyd 1995), LMAs have several important advantages over rival operationalizations of marriage markets. First, LMAs are constructed around journey-to-work patterns and represent the spatial boundaries within which daily social action occurs. This quality makes LMAs a clearly superior representation of marriage markets than larger geographical areas such as states or nations. Second, unlike counties, LMAs can intersect state bound-

aries and, unlike Metropolitan Statistical Areas (MSAs), they encompass the entire U.S. population. Moreover, the microlevel PUMS-D file provides the necessary detail with which to compute appropriate measures of the quantity and quality of spousal options.

In addition to concerns about the proper level of geography used to define the local marriage market, issues of the appropriate measurement of prospective spouses must also be addressed. Clearly, not all individuals participate in the same marriage market. Two of the primary characteristics that segment marriage markets in the U.S. are age and race. Although significant differences in spousal ages may occur, they represent only a small minority of all marriages, with the overwhelming majority of people marrying individuals who are of roughly the same age. This is particularly true among younger cohorts of men marrying for the first time (Schoen & Weinick 1993). The modal pattern is for men to marry women approximately 2 years younger than themselves. And the vast bulk of marriages involve husbands and wives of the same race. Accordingly, when calculating the number of potential wives available to each male respondent, we require that "suitable" partners be single, of roughly the same age (see below), of the same race, and part of the noninstitutionalized population. Specifically, the ratio of potential spouses in each respondent's local marriage market is calculated as

$$RPS_i = \frac{\sum_{i-5}^{i+1} F_i}{\sum_{i-3}^{i+3} M_i} * 100 \qquad (1)$$

where RPS_i is the race-specific ratio of potential spouses for each male respondent age *i*, F_i is the number of unmarried females age *i* available to each respondent in his local marriage market, and M_i is the number of unmarried males age *i* in the respondent's local marriage market with whom he must "compete" for the females in the numerator. Because this article is concerned with the marital behaviors of men, we define the number of potential mates as the number of available females divided by the number of available males, multiplied by 100. This is simply the reciprocal of the traditional sex ratio. Thus, the relevant sex ratio for each male NLSY respondent is based on 7-year age groups in which men choose potential wives who are, on average, two years younger. For example, the relevant ratio of potential spouses for a 25-year-old white respondent is the number of single white females 20 to 26 years of age divided by the number of single white males 22 to 28 years of age. These ratios are calculated separately for each NLSY respondent across each of the six years covered in the analysis and are therefore sensitive to changes in respondents' ages as well as changes in their geographical location. Because these ratios are also based on broad seven-year age intervals, they are preferable to measures based on narrower age ranges (Fossett & Kiecolt 1991). And, while undercount of African American males in the 1980 census was not trivial, Fossett and Kiecolt (1991) demonstrate that such an underreporting will not distort spatial differentials or bias the observed effects of marriage market characteristics on processes of family formation.

We make two modifications to this sex ratio. First, so as not to treat very young females as eligible for marriage, the ratios are truncated slightly at the youngest ages. Specifically, the ratios of potential spouses for men age 18 and 19, respectively, are the number of females 16 to 19 divided by the number of males 18 to 21, and the number of females 16 to 20 divided by the number of males 18 to 22. Second, values of the ratio of potential spouses below the 5th and above the 95th percentile are recoded to those points in the age-race-specific distributions in order to reduce the impact of extreme observations, which most likely occur because of sampling error in smaller LMAs. In our sample, the "average" observed black marriage market, which is simultaneously delimited by LMA and age group, contains 274 unmarried black women and 215 unmarried black men. The corresponding counts for the typical white NLSY respondent in our sample are 689 unmarried white women and 690 unmarried white men. In the present analysis, 170 LMAs contain at least one black male NLSY respondent, while 332 LMAs contain at least one white NLSY respondent.

Two features of the research design may militate against finding significant effects of contextual explanatory variables for blacks. First, the comparatively small number of LMAs containing a black male respondent means that the full range of marriage market conditions experienced by the black population will not be captured in these data. If measures of mate availability vary by the likelihood that an LMA is represented in the analysis — e.g., if LMAs with small black populations (and thus no NLSY respondent) have unusual values on the sex ratio measures — then the variation in these variables will be truncated. Second, estimates of the values of the contextual variables may be less reliable for blacks than for whites because of the smaller sample sizes used to compute the former. Therefore, the observed contextual effects on black men's marital timing should be interpreted cautiously.

As noted earlier, it seems likely that, in addition to their relative supply, the social and demographic characteristics of potential wives might also influence young men's transition to first marriage. Particularly important are the numbers of women who are employed, have high educational attainments, and are enrolled in school. Accordingly, we compute from the PUMS-D file the percentage of unmarried women in each respondent's marriage market who are currently employed, have at least some college education, and are enrolled full-time in school. That is, these three indicators of the "quality" of potential wives are the percentages of women in the numerator of each respondents' sex ratio who have these characteristics. These time-varying covariates are measured in 1980 and are attached to each record by the respondent's residence at each annual interview in the same manner as the ratio of potential mates described above.

Two additional characteristics of the local marriage market are merged with the individual NLSY records. These are the population size of the LMA in which the respondent resides and the average value of state AFDC payments. Each is allowed to vary as the respondent changes residence from year to year. LMA population size is obtained from the PUMS-D file and included in the analysis because past research suggests that individuals who reside in heavily populated areas experience lower probabilities of marriage (McLaughlin, Lichter & Johnson 1993). Average AFDC payments are obtained from the *County and*

City Data Book (U.S. Bureau of the Census 1983). If AFDC payments provide women with alternatives to marriage, as the literature suggests, then men should find it harder to locate a desirable and willing marriage partner in geographical areas with higher average AFDC payments.

INDIVIDUAL-LEVEL COVARIATES

The remaining explanatory variables reflect economic, social, and demographic characteristics of the male respondents. Most of these variables also appear in prior analyses of men's marital timing (Goldscheider & Waite 1986; Mare & Winship 1991; Oppenheimer, Kalmijn & Lew 1993; Teachman, Polonko & Leigh 1987). Indicators of socioeconomic status are respondent's total annual income (in thousands of dollars), number of weeks worked in the year preceding the interview, whether the respondent owns his own home, and years of completed schooling. Full-time school enrollment and whether the respondent resided with both biological parents at age 14 are both measured by dummy variables. Finally, to examine possible regional differences in the propensity to marry, we include a dummy variable for southern residence. With the exception of respondent's childhood family structure, each of these explanatory variables is treated as a time-varying covariate, measured at each annual interview.

METHODS

The analysis employs a discrete-time event history approach (Allison 1984). A discrete-time, rather than a continuous-time, model is preferred largely for the ease with which time-varying covariates can be incorporated. We constructed a person-year file containing 17,094 records, based on the marital experiences of the 3,907 men. Each observation corresponds to a calendar year. Time-varying covariates are defined at the beginning of each annual interval. Only observations at risk of experiencing a first marriage are included in the analysis. The dependent variable is a binary variable indicating whether the respondent marries during each annual interval. Logistic regression models are used to assess the impact of marriage market characteristics and other explanatory variables on the probability of men's first marriage transitions (Yamaguchi 1991).

Results

Figure 1 presents life-table estimates of the cumulative percentage of respondents marrying by a given age, separately for white and black men. As anticipated, there are substantial differences in marriage propensities between white and African American men. Roughly 73% of white males are expected to marry by age 28, compared to only 48% of black males. These estimates are generally consistent with cross-sectional census data indicating sharp racial differences in men's marital status (U.S. Bureau of the Census 1985) and are also similar to previously observed racial differences in marital timing among young cohorts of females (Lichter et al. 1992). The racial difference in the transition to first marriage is further demonstrated by Table 1, which displays the means and

standard deviations, by race, for all variables included in the event-history analysis of men's transition to first marriage. These person-year observations demonstrate that, among those in a position to marry, white men are nearly three times as likely as African American men to marry during any given year.

Table 1 also demonstrates that black and white men search for prospective partners in very different marriage markets. As indicated by the difference in the mean ratio of potential spouses, black men enjoy a marriage market that contains a larger number of potential wives. The pool of eligible black women is, on average, 30% greater than the pool of eligible black men, while the ratio for whites approximates parity. White men, however, hold a relative advantage in the economic "quality" of single women in their local marriage market, measured here as the percentage of females who are employed or who have some postsecondary schooling. More of the women in white men's than in black men's marriage pool are employed and have at least some college education.

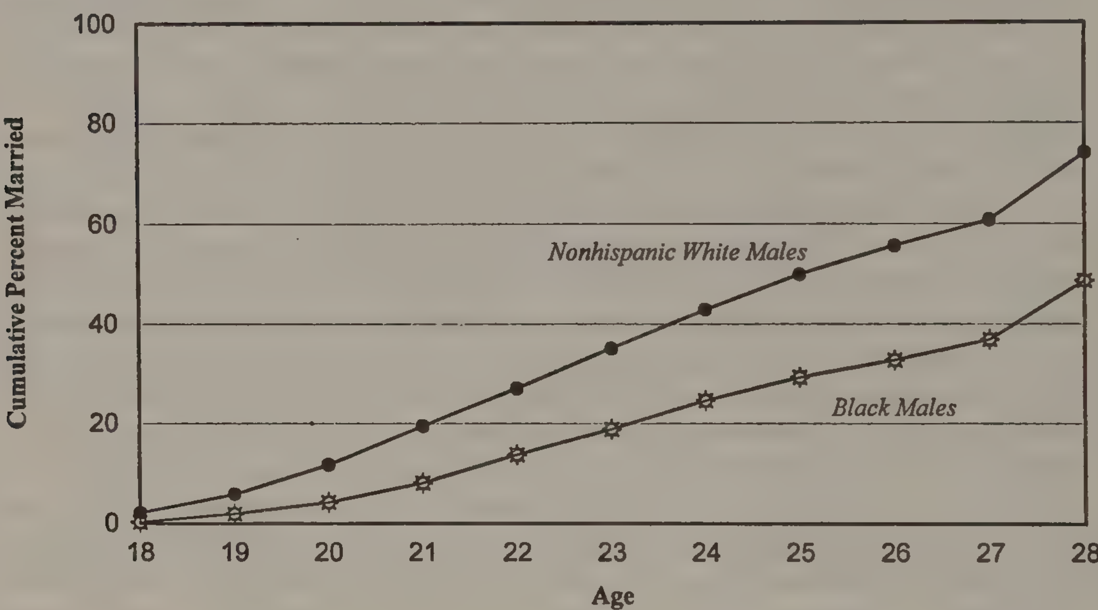
Consistent with prior research, white men also hold a decided advantage on the indicators of socioeconomic status (Mare & Winship 1991). Not surprisingly, white males tend to have higher annual incomes, have steadier employment, have more education, and have a greater probability of owning their own homes — although this latter endowment is relatively rare for both white and black respondents, most likely reflecting the relative youth of the sample. Such characteristics should reflect favorably on both the probability that men will choose to marry and, concomitantly, that they will find a willing partner.

Table 2 presents event-history models of white men's transition to first marriage. Model 1 is typical of previous individual-level analyses of men's marital entry that do not include measures of marriage market characteristics (e.g., Goldscheider & Waite 1986; Teachman, Polonko & Leigh 1987). Of the sociodemographic characteristics, school enrollment significantly impedes the transition to first marriage, while residence in the South enhances the likelihood of marriage. Growing up in an intact family is not significantly related to the timing of white men's first marriage. All four indicators of socioeconomic status significantly influence the annual probability of marriage: income, weeks worked, and home ownership significantly hasten the entry into marriage, while high levels of educational attainment delay it.

Model 2 in Table 2 adds the local marriage market characteristics and other contextual variables to the previous model. The addition of these variables significantly improves the model's ability to predict white men's transition to first marriage. Two of the marriage market characteristics — the ratio of potential spouses and the percentage of women who are employed — have significant effects. The relative number of eligible women in the local marriage market increases white men's annual probability of marriage. This effect is contrary to Guttentag and Secord's (1983) theory of imbalanced sex ratios but is consistent with a marital search model of mate selection. The larger the pool of eligible women, the greater the likelihood that men will marry.[4]

Despite recent evidence suggesting that men prefer wives who are active in the labor force (Mare & Winship 1991; South 1991), model 2 of Table 2 suggests that men are significantly less likely to marry when there is a relatively high percentage of single females in their local marriage market who are employed. As argued above, the financial independence that employment affords females

FIGURE 1: Life Tables Estimates of the Cumulative Percent Married by Age: Non-Hispanic White and Black Males Ages 18-27, 1979-1984



likely reduces women's incentive to marry and thus diminishes the probability that a young man will find a mate amenable to marriage (Goldscheider & Waite 1986; Preston & Richards 1975; Teachman, Polonko & Leigh 1987). The negative coefficient for average AFDC payments provides further support for this "independence effect." Men's likelihood of marriage is lower in counties with relatively generous welfare payments. However, neither the percentage of unmarried females with high education in the local marriage market nor the percentage enrolled in school significantly affects white men's marital timing. Finally, the effect of the remaining contextual variable, population size, is also significant and in the expected direction. The size of the LMA in which the respondent resides is inversely associated with the annual probability of marriage among white men.

Table 3 presents parallel analyses for the African American men in the sample. Again, model 1 is typical of previous studies that focus on individual-level determinants of the transition to marriage. As is the case for white men, school enrollment increases, while southern residence decreases, the likelihood of marriage. Socioeconomic characteristics appear to be important predictors of black men's marital timing. High income and home ownership both enhance significantly black men's probability of marriage. Unlike their white counterparts, however, educational attainment does not significantly affect black men's risk of marriage.

Model 2 in Table 3 adds the local marriage market characteristics and other contextual variables to the previous model of black men's transition to first marriage. Marriage market characteristics fail to emerge as significant determi-

nants of young black men's entry into marriage. As was the case among white men, however, the coefficient for the ratio of potential spouses is positive, and the coefficient for the percentage of single females in the local marriage market who are employed is negative. And, while these coefficients are not significantly different from zero, they are also not significantly different from the analogous coefficients for white men. One other contextual variable in model 2 — average AFDC payments — exhibits significant effects. As in the effects among white males, the size of average AFDC payments decreases black men's marriage probabilities, supporting a "female independence" model. LMA population size, in contrast, does not significantly influence the likelihood that black men will marry.

The analyses presented in Table 4 assess the degree to which racial (i.e., black versus non-Hispanic white) differences in young men's marital timing can be explained by racial differences in the independent variables. These equations are based on a pooled sample of person-year observations for both black and white respondents. The first equation in Table 4 includes as explanatory variables only the dummy variables for age and race. Exponentiating the coefficient for race in this equation implies that the risk of marriage among black males is only 41% ($e^{-.90}$) of the risk for white males. This difference is quite similar to the racial difference in young *women's* marriage probabilities observed by Lichter et al. (1992). The second equation in Table 4 adds the individual-level explanatory variables to the first equation. Controlling for these variables increases slightly the racial difference in the risk of marriage such that, net of these effects, black men are 37% ($e^{-.99}$) as likely as white men to marry in a given year. The third equation incorporates all the explanatory variables as predictors and, again, the racial difference in the risk of marriage tends to increase. In the face of all controls, the net risk of marriage for blacks is only 25% ($e^{-1.37}$) of the risk for whites. As a whole, then, racial differences in the explanatory variables tend to suppress, rather than to explain, racial differences in young men's marital timing.

Of course, the explanatory variables include both factors that might explain the racial difference in marriage probabilities and also factors that might suppress this difference. Variables that act to suppress the difference are education, school enrollment, average amount of AFDC payments, and percentage of females employed. Specifically, relative to white men, black men have lower levels of education and school enrollment and fewer employed women in their marriage markets, and they tend to live in areas with lower AFDC payments. In turn, each of these variables tends to reduce the likelihood of marriage. Hence, once these variables are controlled, the (standardized) racial difference in marriage probabilities grows larger. To a lesser extent, the racial difference in mate availability also "suppresses" the racial difference in marriage; black men have greater marriage opportunities and, in the sample as a whole, these opportunities tend, albeit modestly, to increase the likelihood of marriage.

However, three variables included in the model — income, weeks worked, and home ownership — could conceivably account for some of the racial difference in marriage, given that black men have lower means than white men on these variables and that all three variables hasten entry into marriage. But

racial differences in these three variables do little to explain the racial difference in marital entry. Adding only these three variables to the first equation of Table 4 reduces the coefficient for race from -.90 to -.76 (equation not shown), the latter figure implying that, even net of racial differences in income, weeks worked, and home ownership, black men experience a risk of marriage less than half that of whites ($.47 = e^{-.76}$). In short, it appears that very little of the racial difference in the propensity to marry can be attributed to racial differences in demographic, socioeconomic, or marriage market characteristics.

Conclusion

Patterns of U.S. family formation are changing as many individuals delay their first marriage or remain permanently single. Most theoretical and empirical investigations of marriage, however, emphasize only factors that affect women's decision to form conjugal unions. Consequently, the determinants of men's marital timing have received little attention. This neglect of factors influencing men's entry into marriage is especially problematic given evidence that young men express a greater reluctance to marry than do young women (South 1991). This analysis begins to bridge this gap in the literature by investigating the social context in which men make marital decisions. The primary focus has been on both the quantity and quality of the pool of eligible women in a man's local marriage market as determinants of men's transition to marriage. The results suggest that, at least for non-Hispanic white males, the probability of marriage increases as the number of single females increases. Such findings support a marital search model of mate selection that predicts that individuals will be more likely to marry when they encounter relatively numerous spousal options. A surplus in the quantity of females facilitates men's marital transitions by enhancing their assortative mating process. No support was found for theories of imbalanced sex ratios (e.g., Fossett & Kiecolt 1993; Guttentag & Secord 1983) that argue for the opposite dynamic, namely, that a surfeit of eligible women increases men's desire to avert marriage, thereby delaying such transitions.

The results also suggest that women's economic independence may serve as a deterrent to men's marriage formation. In general, marriage markets that are characterized by a high percentage of women who are employed and markets that have high average AFDC payments significantly decrease men's annual probability of marriage. Both these variables may represent factors that enable women to establish their economic independence from men and provide them with alternatives to the traditional roles of wife and mother. Within such marriage markets men may find it increasingly difficult to find a partner amenable to marriage. Women's labor market prospects may, however, have two offsetting effects. They may increase a woman's attractiveness as a potential wife (South 1991), while simultaneously reducing her economic incentives to marry. If these conflicting effects exist, it appears that the latter outweighs the former within the non-Hispanic white population. These effects may, however, counteract each other within the black population, thus leading to nonsignificant effects of female employment on the probability that black men will marry (Mare & Winship 1991). Further support for a female independence effect is

provided by the negative effect of AFDC payments on marriage probabilities. Both white and black men are less likely to marry in marriage markets that are characterized by high average AFDC payments.

This study also reveals significant effects of men's own economic and demographic characteristics on the timing of marriage. In general, economic resources such as income, employment stability, and home ownership accelerate the transition to first marriage, while school enrollment and high levels of educational attainment delay marital entry. The impact of men's economic resources suggests a partial reinterpretation of studies demonstrating a positive effect of the supply of eligible men in the local marriage market with desirable economic attributes on *women's* marital timing (Fossett & Kiecolt 1993; Lichter, LeClere & McLaughlin 1991; Lichter et al. 1992; South & Lloyd 1992b; Wilson 1987). These studies assume, either implicitly or explicitly, that the areal supply of men with valued economic resources increases women's propensity to marry because women prefer these characteristics in a husband, an assumption buttressed by survey data on women's mate selection preferences (South 1991). But this effect may also occur because economic resources increase *men's* propensity to marry, and thus the probability that a young woman will find in the local marriage market a man amenable to marriage. That is, in local marriage markets that contain a relatively high percentage of economically advantaged men, the marital preferences of both sexes reinforce each other, thereby increasing women's (and men's) marriage rates. This is in contrast to the situation described above, in which men's preference to marry employed women may be overridden by employed women's desire to delay marriage.

Finally, although several of the explanatory variables considered here exhibit significant effects on the timing of young men's transition to first marriage, very little of the pronounced racial difference in men's marriage propensities can be attributed to racial differences in socioeconomic or marriage market characteristics. In fact, standardizing for *all* the characteristics considered here increases, rather than diminishes, the racial difference in young men's likelihood of marriage. As with racial differences in female marriage rates (Bennett, Bloom & Craig 1989) and other dimensions of family structure (Morgan et al. 1993; Ruggles 1994), the racial difference in men's marriage propensities admits no simple explanation. While racial differences in economic factors account for some of the current difference and recent divergence (Mare & Winship 1991) in black and white men's marriage rates, they still leave most of the difference unexplained. Consequently, recent explanations have attempted to situate these broad racial differences within the unique culture and history of African Americans. Cherlin (1992), for example, suggests that blacks responded to a society-wide weakening of the institution of marriage and shifts in labor demand by drawing on the extended kinship networks that have historically been a significant component of the African American cultural repertoire. The reliance on extended kin provided resources that allowed blacks, more than whites, to delay or avert marriage in the face of societal changes inimical to the formation of nuclear families. However, this cultural explanation seems most relevant to explaining the retreat from marriage among black women; it is less clear how the availability of extended kinship ties would affect black men's marital propensities.

An alternative, but not incompatible, cultural explanation for racial differences in marriage emphasizes black men's attachment to peer groups whose values depreciate marriage. According to Anderson (1990), industrial restructuring has sharply curtailed the financial prospects and, consequently, marital prospects for inner-city black men. In turn, these limited marital prospects generate subcultural values that reject middle-class norms of marriage. While these values are initially developed and promulgated among lower-income groups, it seems reasonable to suggest that the strong attachment to peer groups among black men in general may transmit these values to black men having greater resources for marriage. Moreover, black men's low marriage rates, coupled with the tendency for friendship patterns to be homogamous with respect to marital status, imply that marriage will deteriorate peer group ties more among black than among white men. In short, we suggest that deteriorating economic prospects generate a rejection of marriage and that, because of strong peer group ties, these values diffuse throughout the population of young black men, even to those with sufficient resources for marriage. In contrast, peer group values of white men appear to be less averse to marriage (South 1993). Thus, among young men with similar resources for marriage, black men will be less motivated than white men to marry, as our results imply. If this explanation is correct, then studies of the impact of peer group attachment and the marital attitudes of significant others may prove useful in explaining the racial difference in the timing of young men's transition to marriage. In any event, it seems likely that a comprehensive explanation for the racial difference in young men's marital timing must look beyond demographic and economic differences to encompass social-psychological and cultural differences in how black and white men view the institution of marriage.

Notes

1. In one of the few investigations of this issue, Fossett and Kiecolt examine the effects of mate availability on marriage prevalence among African American men across nonmetropolitan Louisiana parishes (Fossett & Kiecolt 1990) and U.S. metropolitan areas (Fossett & Kiecolt 1993). In the former study, under the assumption of a linear relationship, they find positive associations between the sex ratio (men per 100 women) and the percentage of black men who are currently married, a finding consistent with Guttentag and Secord's (1983) theory of imbalanced sex ratios. Across metropolitan areas, however, they find that the sex ratio is inversely associated with black men's marriage prevalence, a finding more consistent with marital search theory. An important finding in both studies is the suggestive evidence that the association between mate availability and men's marriage prevalence is curvilinear, with the highest prevalence occurring where the numbers of men and women approach parity, and lower prevalences occurring in marriage markets where one sex outnumbers the other. Neither study, however, examines the effects of mate availability on the marital behavior of white men.

2. Prior studies have generated somewhat equivocal findings on the impact of female employment and education on women's marriage. Aggregate studies, using data on U.S. metropolitan areas or marriage markets, generally report *inverse* effects of women's labor force participation rate and mean years of school completed on the female marriage rate (Fossett & Kiecolt 1993; Freiden 1974; Lichter, LeClere & McLaughlin 1991; Preston & Richards 1975), while individual-level studies tend to find modest but *positive* effects of women's employment and educational attainment on their likelihood of marriage (Goldscheider & Waite 1986; Lichter et al. 1992; Waite & Spitze 1981). Whatever the reason for this incongruity, the aggregate analyses appear to be more relevant for the present analysis, and our hypothesis of inverse

effects of women's levels of employment and education on men's marital timing is consistent with this research.

3. The racial difference in marriage rates does not appear to be a consequence of higher nonmarital cohabitation rates among blacks than among whites. In fact, net of other factors, the likelihood of cohabitation is lower among African Americans (Bumpass & Sweet 1989).

4. Some interpretations of the sex ratio thesis imply a curvilinear relationship between the supply of potential wives and men's propensity to marry, with both a deficit and a surplus of mates inhibiting men's desire to marry and men's marital propensity peaking when the sex ratio approaches parity (Fossett & Kiecolt 1993). In additional analyses, we tested for this hypothesized nonlinearity with a polynomial response function, including as independent variables (in the equations in Tables 2 and 3) both the ratio of potential spouses in its original metric and its square. The coefficient for the square of the sex ratio was consistently nonsignificant, providing no support for the hypothesized curvilinear relationship.

Book Reviews

Social Change and the Experience of Unemployment.
Edited by Duncan Gallie, Catherine Marsh, and Carolyn Vogler. Oxford University Press, 1994. 373 pp. $59.00.

Reviewer: GARY P. GREEN, *University of Wisconsin, Madison*

Social science research on social change usually relies on one of two methodological approaches — analyses of large samples of a population, or case studies of communities, families, or individuals. Each has a set of strengths and weaknesses. This book provides an excellent model for bridging the gap between the two approaches. *Social Change and the Experience of Unemployment* is part of a series of volumes originating from the Social Change and Economic Life Initiative, a multidisciplinary project funded by the British Economic and Social Research Council that examines the consequences of the economic restructuring process on employer strategies, the worker's experience of unemployment, and the dynamics of household structures.

This volume is primarily concerned with the social causes and consequences of unemployment. Large-scale surveys were collected in six areas — Aberdeen, Kirkcaldy, Rochdale, Coventry, Northampton, and Swindon. All of these regions have experienced different patterns of economic and social restructuring. Other volumes in the series examine occupational change, employer strategies, gender segregation, the household, and trade unionism. Unlike many edited volumes, the various chapters in this book are integrated and hold together fairly well.

The authors of the introductory chapters do an excellent job discussing both the growing prevalence of unemployment in England and the different conditions in the six regions under study. Among the substantive topics examined in the book as a whole are the relationship of work attitudes to unemployment, the effects of the husband's unemployment on the wife's work, the effects of unemployment on psychological health, social networks and ties, marital dissolution, and welfare and collectivism. The analysis is timely given the recent interest in the U.S. in many of these topics.

U.S. researchers will value Gallie and Vogler's examination of work attitudes and unemployment. Their analysis is strengthened by the fact that they are able to examine the effects of work attitudes on unemployment over time. One of the major findings is that work attitudes among the employed and unemployed do not differ significantly and that work attitudes do not determine job status. The chapter by Davies, Elias, and Penn on the link between husband's unemployment and wife's labor force participation is also especially strong.

Although this is an impressive piece of work, I do not believe the researchers fully used the available data. Most of the community comparisons are lost in the analyses because the household data are aggregated. Obviously the aggregation was done for statistical reasons, but much of the context for economic and social

restructuring was lost as a result. In addition, because the project was broken down into several topics (e.g., skills, gender segregation, the household), the analyses of unemployment are separate from those of employer strategies, occupational change, and trade unionism. The researchers could have made more significant use of their unique data if, instead of combining the data in ways that resemble a national sample, they had conducted analyses demonstrating the linkage between the various substantive topics and the contextual processes of social change. Such analyses would have made a more valuable contribution to the literature on economic restructuring and unemployment.

Families in Troubled Times: Adapting to Change in Rural America.
By Rand D. Conger, Glen H. Elder Jr., and others. Aldine de Gruyter, 1994. 314 pp. Cloth, $46.95; paper, $23.95.

Reviewer: DORIS R. ENTWISLE, *Johns Hopkins University*

Like many books coming off the press these days, this one has multiple authors — 17 if I count correctly — with various authors assigned responsibility for individual chapters. Unlike many other such volumes, however, *Families in Troubled Times* has a clear focus and a common style — it is indeed a book rather than a compendium of chapters. Also, unlike many books that focus on a single research project, this one contains several chapters in which the research is placed in a larger context.

The focus of the research is on 451 intact families in rural Iowa, of whom many lost farms or farm-related livelihoods in the economic downturn in rural Iowa in the early 1980s. The data come from four members of each family: the father, the mother, an adolescent child, and the sibling closest in age to the adolescent were interviewed and observed.

In addition to a comprehensive description of the hardship-related experiences of the families, one coauthor (Lasley) traces the history of boom-and-bust cycles in agriculture and documents how the crisis in the 1980s led to severe out-migration and a general economic decline in the rural counties in which the study families resided. Lasley places the families in the larger social and economic context of rural America in the 1980s.

In describing how the families adapted to economic losses, Elder and associates describe the emergence of rural ghettos and relate how families made ends meet by cutting expenses and delaying purchases. They note trends toward off-farm employment and how children's work inside and outside the home helped counter adverse circumstances. They also describe the sense of hopelessness that overtook those who bore severe financial hardships. An intriguing chapter by Whitbeck and associates examines how the grandparent generation raised the parents, in particular how psychological weaknesses in the parents, which could be traced to their childhoods, undercut their ability to evoke needed social supports in the hard times of the 1980s.

LISREL-style models reveal, for example, that feelings of depression among wives or husbands were more prevalent in families with lower incomes, with incomes that were declining relative to prior years, with higher debt-to-asset ratios, or with unstable work patterns, although social and family support mitigated the adults' depressive symptoms. Nonetheless, economic stress exacted a heavy toll on marital quality and on parent-child relations. Economic pressures, besides having a

direct relationship to adolescents' adjustment, led to hostility between spouses that spilled over into explosive disciplinary practices with children. Parents' hostility even undercut warm and supportive feelings between siblings.

The collaborative research in *Families in Troubled Times* provides a nice counterpart to the shower of studies beginning to appear on poor families who live in urban settings. It differs from most of them by following traditions established in Elder's earlier work: invoking intraindividual psychological processes to explain behaviors prompted by economic loss, considering more than one parent in the same family, following a carefully defined cohort in a carefully defined social context over time, and, most of all, emphasizing the historical context surrounding these particular persons. In addition, it often pits one structural model against another so as to identify antecedent variables and their paths of influence as precisely as possible.

This book could be used in graduate or undergraduate classes, and it will be worth having over time.

From Redlining to Reinvestment: Community Responses to Urban Disinvestment. *Edited by Gregory D. Squires.* Temple University Press, 1992. 288 pp.

Reviewer: NANCY A. DENTON, *SUNY at Albany*

Two 20-year-old laws inspired what is wonderfully described in this book as "a quiet revolution." The 1975 Home Mortgage Disclosure Act (HMDA) requires the banking industry to release lending data by census tract, and the 1977 Community Reinvestment Act (CRA) defines the affirmative obligation of banks to meet their local community's credit needs. Thus the HMDA provides the data used to determine if the CRA obligation is met. While primarily aimed at researchers concerned with community development, housing, and neighborhoods, this book will also appeal to social scientists interested in social movements and in the effects of law on society. Seldom can the roots of a social movement be so clearly specified, and this movement has many and varied successes to its credit.

The first chapter, by Squires, and the last, by Calvin Bradford and Gale Cincotta, give superb theoretical, historical, and substantive context to the case studies that comprise the seven intervening chapters. Both should be read by everyone interested in the topic, and they would be useful class readings as well. The case studies focus on large cities, primarily in the industrial Northeast (Boston, Pittsburgh) and Midwest (Detroit, Chicago, Milwaukee), but they also include Atlanta and the state of California. Each is interesting and well written. The essence of the movement is the three-way partnership between government, banks, and the community to renew people and places. Both whites and minorities are victims of a system that discriminates against older communities, and they can unite, not in trying to change the system, but in trying to make it work for them. The communities vary in terms of success and failure, goals (banking services, banking location, single-family mortgages, multifamily mortgages, business loans), and strategies (e.g., the role of the media), so the reader gains a complete picture of how the HMDA and CRA can be used to aid neighborhoods.

For all the impressive positive accomplishments and empowerment reported in this work, the volume ends on a downbeat note as one learns how inadequately federal agencies enforce the CRA. Seldom do banks get bad CRA ratings (less than

15 percent of the time), and the regulatory agencies have obstructed the release of data on loans by race within each tract — data that might be used to identify areas on the brink of change for prompt intervention. Moreover, "not only do the regulators endorse the dual housing market, but they are willing to penalize those institutions that take aggressive steps to overcome conventional lending discrimination and act affirmatively on fair housing." As in the case of the 1968 Fair Housing Act, the failure of public policy is not in the laws but in their enforcement provisions and mechanisms. Communities are forced to do the work that a responsible government, one intent on fostering the principles of its own constitution, should do. Fortunately, this book shows that many communities are willing to do just that.

Chinatown: The Socioeconomic Potential of an Urban Enclave.
By Min Zhou. Temple University Press, 1992. 275 pp.

Reviewer: JAN C. LIN, *Amherst College*

The socioeconomic vitality exhibited by ethnic enclaves like Los Angeles's Koreatown and Miami's Little Havana has prompted reconsideration of traditional sociological assumptions regarding the urban ecology of immigrant settlement and the structural incorporation of immigrants into American society. Min Zhou's monograph on New York's Chinatown brings these issues into sharp focus as she confronts the assimilation model of the melting pot with the ethnic persistence paradigm of the enclave economy thesis.

Rather than viewing ethnicity as a liability that impedes socioeconomic and residential integration into American society, Zhou presents a more nuanced picture of ethnicity as a collective resource that is more enabling than constraining. Disadvantages of working within the ethnic enclave include low wages and exploitative working conditions; advantages include trust and loyalty, protection from societal prejudice and discrimination, viable employment despite limited proficiency in English, on-the-job training, potential for promotion, and opportunities for coethnic pooling of entrepreneurial capital. These tangible forms of social capital augment the workings of physical capital (money) in the enclave economy.

Zhou divides the enclave economy into a protected sector (oriented toward coethnic goods and service activities) and an export sector (oriented to the broader economy). Historically composed of laundry businesses, and replaced recently by the garment industry, the export sector is Chinatown's major source of income, which is recirculated through the protected sector via the Keynesian multiplier. Zhou overlooks the growing role of tourism as a source of export income for the enclave economy (via restaurants, curio shops, and jewelry stores).

Evidence for Zhou's study is primarily derived from field interviews and the public-use microdata sample (PUMS) of the 1980 U.S. census. Zhou uses a "returns on human capital" labor market perspective, following a methodology pioneered by Alejandro Portes in his examinations of Miami's Cuban and black enclave economies. Results of the analyses generally confirm that male enclave workers are able to gain positive returns on human capital (particularly college education). No specific differences are found, however, when comparing returns for participants inside or outside the enclave, or when comparing employees with entrepreneurs. Turning to gender, Zhou significantly finds neutral or negative returns on human

capital for women, leading to the conclusion that the broader positive functions of the enclave are partially derived from patriarchal exploitation.

Zhou suggests that the enclave "converts economic gains into residential ones," since a common sign of upward mobility among Chinese immigrants is the purchase of a home in New York's outer boroughs, commonly in "satellite Chinatowns" in Queens and Brooklyn. An analysis of data from the summary tape file of the 1980 census confirms this "ethnic resegregation" in the outer boroughs, which departs from traditional human ecological predictions that spatial assimilation will accompany socioeconomic mobility. There are also indications that satellite Chinatowns are absorbing some newer, poorer immigrants as well.

Finally, while Zhou correctly observes that overseas Chinese capital is a double-edged sword that augments the enclave economy while producing land-use conflict, she generally does not adequately contextualize her study in a world economy in which labor and capital are increasingly mobile. Her treatment of political ramifications is also weak, despite Chinatown's growing significance as a place of labor and protest action, a community-planning district for public officials, and a voting bloc in municipal elections. The sophisticated statistical evidence Zhou marshals in advancing ethnic enclave theory, however, makes her monograph one of the more important recent contributions to urban sociology, stratification theory, and race and ethnic studies.

The Population of Modern China.

Edited by Dudley L. Poston Jr. and David Yaukey. Plenum Press, 1992. 757 pp. Cloth, $79.50; paper, $44.50.

Reviewer: ELLEN EFRON PIMENTEL, *University of Illinois at Chicago*

The goals of this volume are laudable. Its editors aim to provide a compilation of present-day knowledge on the population of modern China suitable for students of world population and demography. The book is divided into eleven major sections covering such substantive areas as basic size and distribution, fertility trends and policies, international and internal migration and urbanization, mortality, marriage and family, and the process of demographic research in China. Each section contains two or three essays and includes a short introductory statement by the editors.

Given the explosion of recent research on Chinese population processes and policies, any book that promises to bring together major work on these topics sounds inviting. How well does this one fulfill its promise? Sociologist Nan Lin asserts in the foreword that a comprehensive appraisal of what is known about the Chinese population has so far been hindered by the lack of a single volume in which essential facts and analyses are made readily available. Perhaps this absence can be attributed to the heavy flow of data from China that continued into the late 1980s and early 1990s. In the context of the present volume, however, no such void exists, since the editors have largely reprinted essays using data from the early 1980s (with the exception of Poston's epilogue, which uses 1990 census data), covering much the same ground as Judith Banister in her excellent and comprehensive 1987 book, *China's Changing Population*. Indeed, Poston and Yaukey have reprinted four of Banister's 10 chapters, though her book is readily accessible. Given that the current volume was published late enough to include preliminary data from the 1990 census, it is curious that the editors did not delay publication in order to move

beyond Banister's contributions into more recent developments in Chinese demography.

More seriously, anyone interested in the goals outlined in the foreword — to examine how the Chinese population has been shaped by the interplays of political ideology and institutions, economy, government policies, sociocultural traditions, and ethnic divergences — will be unsatisfied. The breadth of the volume does not readily allow for such investigation. Though some essays do delve into these issues, the book is mostly a barrage of descriptive demographic data with no connecting theme or theory. While the value of having such a large quantity of data in one place is unquestionable, the lack of connecting themes makes the book seem somewhat disjointed and confusing.

The very attempt to provide information on such a wide variety of topics contributes to the sense of confusion. Each topic necessarily receives only superficial coverage. For example, except for the rather weak selection by Tien — an interview with Peng Peiyun — the section on fertility policy gives the reader little sense of the raging debates that have swirled around the implementation and consequences of the one-child policy, or of the resultant changes in policy throughout the 1980s and early 1990s. The demographic and social implications of differential regional implementation of the population policy are also ignored.

If one sticks to the very narrow goal of introducing students to the study of Chinese demography and to the basic findings of research in this field, then the book can be considered adequate to the task. Certainly this collection of essays includes many fine examples of basic data analysis from the 1982 census in particular, as well as other commendable studies from the 1980s. Especially effective is the combination of essays emphasizing empirical data on population trends and levels with essays fleshing out such background issues as ethnic identification and classification, problems of defining urbanization, and so forth. Greenhalgh's contribution, a behind-the-scenes look at how demographic research and collaborative work are carried out in China, is particularly admirable. Students of demography all too often are exposed only to the demographic facts and not to the processes by which those facts are brought to light or to the problems inherent in collecting demographic data.

The Rise and Fall of Catholic Religious Orders: A Social Movement Perspective.
By Patricia Wittberg. SUNY Press, 1994. 423 pp. $59.50.

Reviewer: DAVID YAMANE, *University of Wisconsin at Madison*

Although not without importance in the Catholic Church and society at large, the decline of Catholic religious orders has garnered little scholarly attention to date. Wittberg's book begins to fill this significant gap in the literature by providing an interpretation of religious orders as recurring movements of "virtuoso" spirituality. While the longest section of the book explores the rise of Catholic religious orders, the author's interest is clearly driven by their contemporary fall. Thus Wittberg opens by establishing the extent of the current crisis, offering some startling statistics: in the past 30 years the number of nuns and nonordained male religious in America has fallen over 50 percent; currently no new members are applying to 54

percent of all women's religious communities; and in 1990 the median age of nuns was 65.

To explain these statistics and the past 16 centuries of cyclical mobilization and demobilization, Wittberg draws on a variety of theoretical perspectives: resource mobilization theory to understand the material support needed in successful religious movements (chapters 4 and 5), frame alignment theory to understand the importance of ideology in successful mobilization (chapters 6-8), and work on commitment mechanisms in intentional communities (Kanter, Zablocki) to understand the internal dynamics of successful religious movements. She treats these bodies of scholarship as theoretical toolkits from which to draw the conceptual resources necessary to shed light on her evidence.

Wittberg does not, however, use her evidence to shed light on the theories. Consequently she passes over opportunities to make theoretical progress by specifying relationships between macrolevel processes (e.g., ideological frame alignment) and microlevel processes (e.g., communal commitment mechanisms), or between resources and ideology. In this regard *The Rise and Fall of Catholic Religious Orders* compares unfavorably to recent books on related topics, such as Finke and Stark's *The Churching of America* or Burns's *The Frontiers of Catholicism* (though it should be noted that Wittberg nowhere claims to be making a theoretical contribution).

Wittberg appropriates Weber's concept of "virtuoso" religiosity, which highlights the differential ability and willingness of individuals to pursue and attain sacred values. In the Catholic Church, religious orders are one of two institutionalized forms of virtuoso religiosity (diocesan priesthood being the other); thus new communities of religious are instances of successful movements of religious virtuosi. Wittberg identifies six varieties of religious virtuosi in the Catholic Church from the fourth through the twentieth century — desert monks, medieval monastics, Mendicants, Beguines, members of apostolic orders, and members of teaching congregations — each defined by the ideological frame expounded in promoting its innovative form of religious virtuosity.

In part 2 Wittberg takes the rise of these movements as her *explanandum* and seeks to identify the causal factors underlying their success. She draws attention to a variety of material and nonmaterial factors, both environmental and internal to the group, including demographic pressures (e.g., a shortage of marriageable men); support of ecclesiastical and secular authorities; an ideology resonant with the culture of the time and addressing a felt need or strain among some members of the population; opportunities provided by religious orders for education, financial security, and social status; social networks for evangelization; and basic material resources such as food, clothing, and shelter. While she invokes an array of factors and conditions suggested by social movement theory that are implicated in the successful establishment of religious orders, because there is no variance in her dependent variable (i.e., she does not consider any cases of unsuccessful movements to found religious communities), one cannot assess the relative importance of any of the factors.

Part 3 acts as a transition between the second and last sections. In it Wittberg suggests that the same factors that account for the rise of religious orders also determine their fall. As a prelude to her consideration of the contemporary period of decline, she highlights resource deprivation, frame dealignment, and the decay of communal commitment mechanisms as factors in the fall.

Part 4 is the most interesting. Wittberg's sustained treatment of developments during a single time period in a single national context — the U.S. in the postwar era — is more satisfying than her cursory coverage of the first 16 centuries of Catholic religious life throughout the Western world. She convincingly argues that contemporary religious orders in the U.S. find themselves facing extinction owing to a simultaneous delegitimation of the root ideology that had previously sustained them, a corresponding redefinition of everyday behavioral expectations toward individual preference and away from corporate commitment, and a loss of key resources such as ecclesiastical support and new recruits. Although Wittberg — herself a Sister of Charity — concludes by admitting a personal desire to see her own religious order avoid such a fate, if her analysis is correct, she and her fellow supporters of Catholic religious life have their work cut out for them.

This book does many things well. Among its strengths are its treating a previously neglected but consequential historical phenomenon, and its cross-national and historical breadth, which gives a sense of the diversity and importance of the form of religious expression Wittberg explores. Useful summary tables are interspersed throughout the text, and a brief glossary at the end provides a helpful resource for those not familiar with the language of religious orders.

A Weberian Theory of Human Society: Structure and Evolution.
By Walter L. Wallace. Rutgers University Press, 1994. 335 pp. $59.00.

Reviewer: DAVID NORMAN SMITH, *University of Kansas*

Walter Wallace has written a peculiar book, which appears under the auspices of the Rose Monograph Series of the American Sociological Association. It is neither "Weberian" nor a "theory of human society" in any meaningful sense, despite the promise of its title. Another, more significant eccentricity is Wallace's approach to his topic. His apparent goal is to offer a framework for the analysis of social evolution. Ordinarily a project of this kind entails immersion in ethnology and history, in the manner of Sanderson or Krader. Yet Wallace omits almost every matter of fact, offering instead a vague formal model of "social evolution" — a frankly deductive model that he grounds almost entirely in an idiosyncratic reading of Max Weber. This is a peculiar way to approach history, and an equally peculiar way to approach Max Weber.

Wallace opens by cheerfully confessing that his turn to Weber is prompted in part by a wish to be "relevant." Since Weber is almost universally acclaimed, there is, he reasons, a "prima facie assurance that a Weber-inspired theory is likely to address issues of continuing importance." He quickly concedes, though, that his "integration" of Weber's perspectives "is (of course) not to be found in Weber's published work itself." "I have," he writes, "more than half-invented this integration."

Wallace's move is problematic. Since he works without historical data, he is dependent on Weber for insight into history. Unfortunately, however, his Weber is more than half invented and not a good source of data on the past. The problem is not that Wallace is unable to read or grasp Weber. On the contrary, when Weber says what he wants to hear, Wallace is all ears. But Wallace's intellectual agenda is so all-consuming for him, and so exclusive of other sensibilities, that he seems tone-deaf when Weber shifts into another key. The result is that in many places (e.g., in

his account of the Protestant ethic) Wallace is far from the mark in his exposition of Weber's views. He is so eager to map the "phylogenetically given behavioral structure" of social conduct, for example, that he manages to find little more in Weber's anatomy of asceticism than the implication that the "raw materials for the entrepreneur's spirit of capitalism were already present in the human genetic endowment."

Wallace's exegesis of Weber is so eccentric that his technical grasp of Weber's texts is almost irrelevant. It is, after all, possible to be wrong about Max Weber but right about the world. Yet here, too, Wallace falls short.

To "explain" change, for example, Wallace invokes the category of charisma as an explanatory master key. But his notion of charisma is so vague that the term amounts to little more than a slogan, invoked whenever a "punctuation" in history is observed (or predicted). Wallace is thus reduced to empty generalities, affirming, for example, that his model shows "the possibility of an irregularly repeated process that predicts that *any* established stage of human societal culture is likely, sooner or later, to succumb to outbursts of high-intensity charisma . . . that . . . may then force a relatively sudden transition to a new and different stage — or back to a previous one."

Still, Wallace's outlook is so sunny that his book, for all its faults, has a certain charm. It is hard to resist the sheer optimism of an author who can find hope in the prospect of "a worldwide psychical contagion of the charisma of peace, a contagion that can provide a new and radically different punctuation in the future course of history." Yet hope is a poor substitute for historical vision. "Punctuations" do not spring from science, like Athena from the forehead of Zeus. To prepare seriously for the future, one must wrestle with history. Walter Wallace is right, at least, that Max Weber is a likely source of insight on this level.

The Semiotic Self.
By Norbert Wiley. University of Chicago Press, 1994. 263 pp. Cloth, $39.95; paper, $19.95.

Reviewer: ALAN SICA, *Pennsylvania State University*

Norbert Wiley has concluded a notable career as an American (*sic*) social theorist (Donald Levine's jacket blurb correctly notes a Whitmanesque quality to the book) by producing an unusual and challenging assessment of the interior, reflexively monitored monologue/dialogue known in simplified form to most theorists as "the self." He does this with multiple goals, from the most minutely micro to the global, and the unusual character of his project reflects a theoretical sweep considerably broader than many others within the so-called social-psychological realm. He probes around within the psyche while at the same time addressing larger political questions, speaking a language in elaborated form originally invented by his two principal inspirations from classical theorizing, Peirce and Mead, neither of whose conceptual innovations stayed carefully within the properly "psychic." That Wiley's "neo-pragmatic" posture invites his readers to reappropriate them both, particularly Peirce's theories of language and being — which accounts for the book's title being changed midstream from a Meadian "The Reflexive Self" to the published version, a change obviously inspired by Peirce — is but one of its virtues.

Wiley points out that Mead probably never read Peirce, and whereas Mead still enjoys an official coterie of theoretical followers under the banner of symbolic interactionism, Peirce is without many champions. Explaining why is not feasible within such brief compass, aside from noting that no matter how difficult, underdeveloped, and imprecise Mead's theorizing about the self/society mix may be, it bespeaks lucidity itself when compared with Peirce's thoughts on similar matters. For Wiley to sail under Peirce's semiotic flag is therefore risky: to the extent that his intended audience does not or will not embrace the latter's basic semiotic theory, Wiley's attempted merger of the two classical titans is jeopardized. Peirce's notions are thorny and represent the height of conceptual and terminological idiosyncrasy (e.g., "the fact that every thought is a sign, taken in conjunction with the fact that life is a train of thought, proves that man is a sign"; "the entire universe is perfused with signs, if it is not composed exclusively of signs"). When his key terms — firstness/icon, secondness/index, thirdness/symbol, the representamen, the interpretant, and orgies of trichotomization — are seriously evaluated for their contemporary utility as semiotic guides, particularly when compared with the reigning models (Saussure, Ogden and Richards, Barthes, Hjelmslev), it comes as little surprise that his lead has not been followed in analyzing consciousness. Furthermore, that Wiley cites a number of standard sources from Mead in his bibliography but not a single one from Peirce is puzzling. He seems to have relied almost entirely on Vincent Colapietro's *Peirce's Approach to the Self* (1989), a 125-page monograph that, while respected by pragmatist philosophers, can hardly be taken as synonymous with Peirce's original work, especially given that the book's avowed goal is to offer a new theory of the "democratic" self on the back of a merger between symbolic interaction and semiotics.

Wiley is nothing if not courageous: "I will argue that this [Peirce-Mead] synthesis has the strongest elective affinity with the times and is the best choice for the contemporary American situation. This argument will have three parts: that democracy works best if it has a theory of the self; that this theory should explain equality, freedom, and the inviolability of the self, and the Peirce-Mead synthesis is especially useful at this particular time in American history." To what extent Wiley's unique message will influence other theorists (or the political culture of America) probably depends as much on the ready understanding of his theory as on the "truth" it may contain. When he writes, "Humans are a triad of triads, and, in addition, the three triads merge into one. . . . I usually refer to them, in dialogical short-hand, as the I, you, and me, though the more precise names are I-present-sign, you-future-interpretant, and me-past-object," or when he explains, "All signs are semiotic triads, consisting of 'sign,' interpretant, and object, but humans are triads in a unique way. They are the signs behind the signs, or . . . bi-leveled signs," a wily (*sic*) blending of the ordinary with the insightful, not unlike Peirce's own conjectures, is clearly on display. And like most efforts at innovation, some time may pass before all its virtues can be known.

Old-Age Security in Comparative Perspective.
By John B. Williamson and Fred C. Pampel. Oxford University Press, 1993. 316 pp. $49.95.

Reviewer: JOHN A. HALL, *McGill University*

Specialized books on seemingly abstruse aspects of social policy rarely gain a general readership. This is often a great pity, because examination of such detail is what allows for high-powered understanding of how states and societies interact. It would be positively shameful for sociologists to ignore this marvelous book, which is a model for practitioners of sociology in almost every way. Substantively, the work is pioneering in that its authors consider within a single compass both advanced capitalist countries and developing states: separate chapters are thus devoted to Germany, the United Kingdom, Sweden, the U.S., Brazil, India, and Nigeria. It is equally striking methodologically: Williamson and Pampel place their essays on comparative historical sociology within the larger perspective of cross-national quantitative analysis, a method they have used in previous work. More generally, the book is exceptionally thorough and cognitively powerful, particularly in the way the authors seek to use data to assess theory.

Analysis begins, and ends, with the evaluation of five general theories of social-policy advance. Considered are the view that the requirements of industrialism dictate policy advance; the theory of social democracy, probably still dominant in the literature, which privileges pressure from below; neo-Marxist theorizings of rational states seeking to preserve capitalism from above; neopluralist views; and the recently influential state-centered analysis. One clear finding is that the social-democratic perspective explains very little. For one thing, it sheds small light on the surprisingly well-developed system of old-age provision in the U.S.; for another, the expansion of provision for old age in Germany has resulted for the most part from pressure from middle-class rather than working-class constituencies. Further, the only reason the perspective makes sense of the Swedish case is that the state encourages organized pressure from trade unions, which the authors suggest may be true of corporatist societies more generally. The authors also find that the theories in question, which variously do help explain policy in advanced capitalist countries, are applicable to the developing world. Just as ethnic division has an impact on policy provision in the U.S., so too does it affect policy considerations in Nigeria and India. At a general level, the neo-Marxist and industrialism-based perspectives best explain the policy decisions of the late developers.

Williamson and Pampel have written a superlatively synthetic book, making use of theory to explain reality, and have provided an absolute model of lucidity and rigorous argument. Still, they concentrate perhaps too exclusively on public provision; any final account of old-age security would also need to examine the ways that tax systems aid private provision for old age — most notably in Japan, analysis of whose idiosyncrasies is sadly missed. Further, the authors accept too readily standard classifications of corporatism, having not absorbed the reasoning and findings of Michael Smith's important *Power, Norms and Inflation* (1992). One wonders, finally, if more attention to purchasing-power parities would have changed the analysis, there being well-known problems with uncritical conversion into the dollar. But these are only minor criticisms of a major achievement.

Take Note

Blieszer, Rosemary, and Victoria Hilkevitch Bedford (eds.). *Handbook of Aging and the Family. Greenwood Press, 1995. 536 pp. $95.00.* Traversing the theoretical and methodological, this multidisciplinary reference examines family relationships and family life. With a focus on families with aging members, boundaries of families are broadly defined. Family life beyond the rearing of children, among members of different households, and among persons who no longer are connected through blood or marriage are considered.

Chen, Lincoln C., Arthur Kleinman, and Norma C. Ware. *Health and Social Change in International Perspective. Harvard University Press, 1994. 508 pp. Paper, $15.00.* The Health Transition Program conducted at the Harvard Center for Population and Development Studies from 1987 to 1990 generated this collection of papers focusing on the social dimensions of health change. The dialogue is interdisciplinary in nature and is oriented towards developing countries. The selections describe patterns of change in health, conceptual and methodological issues, the social dimensions of mortality and illness, and means of promoting health.

Ermisch, John, and Naohiro Ogawa (eds.). *The Family, the Market, and the State in Aging Societies. Oxford University Press, 1994. 239 pp. $42.00.* This combination of economic and demographic analysis explores the consequences of change in family formation and dissolution over the past twenty years. Individual chapters consider the U.S., Europe, and Japan, and are divided into two sections. The first considers market and state influences on family formation and the second concentrates on intergenerational transfers.

Thronton, Arland, and Hui-Sheng Lin. *Social Change and the Family in Taiwan. University of Chicago Press, 1995. 466 pp. $29.95.* The implications of rapid social and economic change for family change are considered. The patterns and causes of change addressed include education, work, income transfers, leisure time, marriage, and living arrangements. Perspectives are interdisciplinary and analyses are organized broadly around two conceptual frameworks — the modes of social organization framework and the life-course perspective.

Erratum

In Denise Kandel's article, "The Impact of Drug Use on Earnings: A Life-Span Perspective," published in the September 1995 issue (74:1), the last sentence of the second paragraph on page 261 should read as follows: "Finally, (c) drug users experience less growth in their wages than nonusers from the late twenties to the midthirties."

Referees

We record our gratitude to our colleagues who assisted us from July 1, 1994 through June 30, 1995. Their reviews of several hundred manuscripts provided a valuable service to the authors, to the journal, and to the profession. The list does not include people who were Editorial Board members during that period.

SOCIAL FORCES

AN INTERNATIONAL JOURNAL OF SOCIAL RESEARCH
ASSOCIATED WITH THE SOUTHERN SOCIOLOGICAL SOCIETY

VOLUME 74: NUMBER 4 JUNE 1996

IN GENERAL

1. Mail manuscripts (5 copies) to: Social Forces, Department of Sociology, Hamilton Hall, University of North Carolina, Chapel Hill, NC 27599-3210.

2. The paper must not be submitted to another journal while under review by SF.

3. Enclose a $15 processing fee. Papers are not reviewed until this fee is paid. The fee is waived for papers solely by currently enrolled students.

4. Manuscripts are not returned to authors.

5. Authors transfer copyright to SF. Permission fees for reprint of articles are split between authors and journal.

PREPARATION OF MANUSCRIPTS

SF Form For review, papers may be submitted in the form used by SF, American Sociological Association or other major sociological journals. Authors of accepted manuscripts are responsible for putting them into SF form.

Format, Organization, and Style Submit 5 clearly legible copies on 8 ½ by 11 good quality white paper. Double space typing throughout. For an accepted paper being revised to fit SF style, leave at least 1" margins; do not justify margins if using a word processor.

Order Organize the manuscript in this order: cover page; abstract; text; endnotes; references; tables; figures.

Cover Page Give title; author(s); affiliation(s); and a footnote (*) indicating name and address of the author to whom requests for offprints or other correspondence should be sent ("Direct correspondence to ___") and acknowledgment (if any) of financial or other assistance.

Abstract On a separate page, preceding the text, write a summary, 125 or fewer words (70 or fewer for a Research Note).

Endnotes Use only for substantive comments, bearing on content. Number consecutively from 1, double space, and append on a separate page.

Tables Type each table on a separate page. Insert a location note — "Table 1 about here" — in the text. For substantive footnotes relating to a table or figure use lowercase letters. Use tabs to separate columns.

Figures Must be artist-drawn, camera ready. Do not send original copy with a manuscript submitted for review. For review, figures may be roughly drawn but they must be neat and legible. For footnotes to figures, use same symbols as for footnotes to tables.

Mathematical Symbols (and others likely to be obscure to compositor) Clarify with encircled words written in the margin.

References in Text Indicate sources as illustrated below:

- when author's name is in text — Lipset (1960); when author's name is not in text (Lipset 1960)
- use page numbers only for direct quotations or specific notes or table — (Braudel 1969:213)
- for more than 3 authors use "et al."
- with more than 1 reference to an author in the same year, distinguish them by the use of letters (a,b,c) with year of publication (1975a)
- earlier publication should precede later publication in brackets with parentheses (Tocqueville [1835] 1956)
- enclose a series of references — in alphabetical order — in parentheses, separated by semicolons (e.g., Adler 1975; Adler & Simon 1979; Anderson, Chiricos & Waldo 1977; Bernstein et al. 1977; Chesney-Ling 1973a, 1973b).

References Following Endnotes List authors alphabetically, by surname. Spell out first names of all authors and editors. For authors with more than one work cited, list works earliest to latest. For articles, next give title of article (caps and lower case), name of journal, volume number, and pagination. For books and monographs, give title, followed by publisher.

Format of References Please spell out the first names of all authors and editors, unless they use only their initials or a first initial and a middle name in the source cited (e.g., Paul Radin, T.S. Eliot, and J. Owen Dorsey).

Elder, Glen H. 1975. "Age Differentiation and the Life Course." Pp. 165-90 in *Annual Review of Sociology*. Vol. 1, edited by Alex Inkeles, James Coleman, and Neil Smelser. Annual Reviews.

BOOK REVIEWS

Who Fought in Vietnam?*

CYNTHIA GIMBEL, *Caliber Associates*
ALAN BOOTH, *The Pennsylvania State University*

Abstract

Using a sample of 4,338 Vietnam-era veterans, several factors indicating biosocial characteristics, race, mental aptitude, antisocial behavior in school, and military history were examined for their effects on (1) risk of combat arms assignment, (2) risk of assignment to Vietnam, and (3) level of combat exposure once in Vietnam. Also considered was the possible effect of general war strategy, as indicated by whether it was early or late in the war. Factors that indexed ability to perform noncombat support jobs had the most significant effect on combat arms assignments and assignment to Vietnam factors; these factors were also significant in predicting combat exposure. Biosocial predispositions to aggression and stress management are also associated with degree of combat exposure. Battlefield strategy also influenced the selection of individuals for combat.

During the Vietnam War, a soldier was not assigned to combât immediately on entry into the military. Instead, combat exposure was the end product of a three stage process that proceeded from job assignment, to assignment to Vietnam, and finally to combat. Assignments at each of these stages either increased or decreased a soldier's risk of combat exposure. These assignments were not entirely random, but rather depended on the characteristics of the individual soldier and the needs of the military at that time. Prior research on this topic has been driven primarily by hypotheses concerning discrimination and thus has focused on race and class as predictors of combat-related assignments or experiences. (See Appy 1993, Badillo & Curry 1976, Martin 1986, Moskos 1970, and Zeitlin, Lutterman & Russell 1973.) Exceptions are Card (1983) and Frey-Wouters and Laufer (1986). In addition, this earlier research examined stages of this process separately and did not account for the influence of predictors on previous stages. (An exception is Martin 1986.) Also, prior research examined issues of selection into combat for either the entire period of the war or for very limited time periods; dramatic changes in both strategic goals and public sentiment that occurred during the course of the Vietnam War have been ignored

 Social Forces, June 1996, 74(4):1137-1157

There are three important questions we would like to consider here. First, were there individual characteristics beyond race and class that increased a soldier's risk of combat by increasing the probability of receiving a combat-related job assignment, assignment to Vietnam, and ultimately, combat experience? Second, at what stage in the process did each of the individual characteristics matter? Third, did the influence of these characteristics vary by time period in the war?

Using a sample of 4,338 surviving Army nonofficers who served between 1965 and 1971, this research employs multivariate analysis to test two models of the influence of personal characteristics on assignment in the military. The potential combatant model states that men were placed in assignments that carried a greater risk of combat because they possessed qualities that would make them better combatants. The potential support staff model states that men were placed in assignments that carried a greater risk of combat because they had characteristics that indicated a lack of ability to handle complex support positions. Each model has associated with it a different labor queue and different variables that are operational at different points in time. We assess these models at each of the three phases in the process from induction to combat by statistically controlling for their influence on the previous phase. The difference in validity of these models according to the time period of the war is also assessed by examining the interactions between the soldiers' time of service and personal characteristics.

We focus on risk of combat exposure among survivors of the Vietnam War rather than all soldiers because our broader interests are in the long-term individual outcomes related to combat exposure. Repeatedly, Vietnam combat veterans have been found to have suffered more negative life outcomes than either other veterans or civilians of the same ages (Frey-Wouters & Laufer 1986; Kulka et al. 1991). These differences, for the most part, have been attributed to combat experience. However, this explanation ignores the life context in which combat occurs. If combat experience were randomly assigned to all men entering the military, then understanding this life context would be irrelevant. However, accepting that combat was not randomly assigned, then understanding its negative life outcomes cannot begin until we learn who was at greatest risk of combat exposure and whether the characteristics that identify these individuals contribute in any way to the later-life outcomes. By identifying characteristics which placed these men at differential risk of combat exposure, we can better understand the relationships between the experience of combat and the preceding and subsequent life experiences. In this study, we do not examine other important issues such as what characteristics predict induction into the military or what factors predict whether or not an individual was killed in combat. We suggest, however, that the variables which predict combat exposure would also predict who is killed in combat. Our study considers soldiers who served in the military and who survived the war and approximately fifteen years of post-military life.

THE MODELS

According to the theory of labor queues, organizations select individuals based on their ranked desirability for the task at hand (Thurow 1975). The military had two competing task queues: combat and support.

Those with greater combatant potential would be selected for the labor queue for combat. Our assumption is that indicators of biological and behavioral predispositions to aggression and good stress management are measures of desirability for combat tasks . Soldiers with these characteristic would not be the only ones who experienced combat but they might have been somewhat more likely to experience combat or to experience more combat than other soldiers.

For the support task queue (associated with noncombat jobs), those who had greater potential for handling complex support assignments would have been selected. While not all support positions involved complex tasks, selection for support could have been based on an assumed need for more complex skills than were required in combat. Desirable characteristics for support staff are mental aptitudes indicating trainability, commitment to the military (indicated by status as volunteer or draftee), and maturity (indexed by age at entry). (See Segal 1989 for a discussion of the military's reluctance to train low aptitude soldiers.)

The assignment of soldiers to a direct combat role was the outcome of a complex process composed of three phases: (1) receiving a combat arms assignment rather than a combat support assignment, (2) being sent to Vietnam rather than to Europe or remaining in the U.S., and (3) experiencing combat in Vietnam. The assignment made at each phase could be based on degree of desirability as a combatant, desirability as support staff, or both. The set of significant factors in the decisions could vary according to the phase since both the requirements and the available pool of personnel differed at each phase. At the outset, decisions were made Army-wide about the large groups of men who were available for assignment. Various characteristics such as test performance, age and draft status are expected to have been important factors because they were readily accessible. At the end of the process (in or near the field of combat), decisions were made at the company or platoon level about a few men. Here, personal qualities such as aggressiveness and ability to handle stress were more readily accessible and thus likely to be considered.

WHO RECEIVED COMBAT ARMS ASSIGNMENTS?

Combat arms assignments entailed direct confrontation with the enemy (e.g., light weapons infantry, armor crewman, field artillery crewman, automatic weapons crewman) and were made at the conclusion of basic training. Other noncombat assignments, such as combat support and combat service support, were made at the same time.[1] In 1968, only 12% of all servicemen were in combat jobs (Baskir & Strauss 1978). The other 88% comprised the complex organization of specialties backing combat soldiers, a significant number of which were in high-skill occupations. Evidence suggests that combat arms jobs were filled predominantly by men with lower mental aptitudes and skills (Baskir & Strauss 1978; Laurence & Ramsberger 1991) who were presumed unable to

handle complex support positions. This assignment policy held even as manpower demands increased. When more manpower was needed for combat roles, the noncombat soldiers transferred to combat often had low IQs (Baskir & Strauss 1978). Heavy demands for manpower also led to the lowering of aptitude and educational standards for entry into the military. During the Vietnam War, this occurred at least four times (Eitelberg 1988). Thus, we would expect that those scoring low on the Armed Forces Qualifying Test (AFQT) would have been more likely to get combat arms assignments than to receive assignment to support positions.

Draftees may not have been preferred for highly skilled support jobs because they were only in the service for 24 months and because they were presumed to be not committed to the military, since they did not volunteer. It was not cost-effective to invest heavily in training a draftee who would only use his skills for a short time. In addition, assigning draftees to combat may have aided in recruitment. One recruiting strategy was to offer relatively safe assignments to those who entered voluntarily for an extended period (Baskir & Strauss 1978). Preferential treatment also may have been given to volunteers in the form of noncombat assignments in the hopes of reenlistment.

A soldier's value to the military might also have been a function of age at entry. Young recruits were expected to have had poor academic performance. Soldiers aged 19 and younger may have appeared to the Army not to be worth the training investment. Perhaps they were viewed as too immature to follow complex instructions, be thorough, work autonomously, or take responsibility for tasks. Thus, they would not have been preferred for complex support positions.

These considerations lead us to the first hypothesis:

Hypothesis 1: Having a low intelligence/aptitude score, being young, and being drafted increased the probability of receiving a combat arms assignment.

If these variables are the primary predictors for receiving a combat arms assignment, then the potential support staff model explains assignment to combat arms better than the potential combatant model. Support for the hypothesis is also consistent with the idea that early large-scale screening of men was based upon readily available status characteristics and test results rather than on qualities that require direct observation to discern. On both counts, combat arms assignments would appear to have been received by default.

WHO WAS SENT TO VIETNAM?

While those with combat arms assignments were in great demand in Vietnam, Army combat personnel also were being sent to other overseas locations such as South Korea and Europe, as well as being kept stateside. Thus, scores on aptitude tests, type of entry, and age at entry may have figured in decisions about assignment to Vietnam. For example, men with high levels of aptitude or education, regardless of assignment, may have been kept stateside to work for officers who wanted reliable clerks or assistants (Baskir & Strauss 1978). Draft status may have affected later timing or location of assignment through its connection to reenlistment. Additional commitment to the military through early

reenlistment on the part of volunteers (spurred by impending assignment to Vietnam) may have insured new noncombat training and thus prolonged avoidance of the war zone for some (Baskir & Strauss 1978). Draftees, however, would have been less likely to reenlist than those who joined voluntarily the first time, and are thus less likely to have benefitted from this. Emotional and work-related maturity (indicated by age at entry) also may have kept some men out of Vietnam. Mature workers might have been preferred for tasks and training that would keep them in the U.S. because they were perceived as better prepared. These points lead us to the second hypothesis:

Hypothesis 2. Having a combat arms assignment, low intelligence/aptitude score, being young, and being drafted increased the probability of being sent to Vietnam.

With the exception of holding a combat arms assignment, evidence in favor of this hypothesis would support the validity of the potential support staff model for this phase of the selection process. Like receiving a combat arms assignment, being sent to Vietnam may have been a default assignment partly brought about by the requirements for massive screening.

WHO ACTUALLY FOUGHT?

The degree of exposure to direct combat in Vietnam was due to many factors which may have been outside either his or his immediate superior's control and thus independent of his personal attributes. For example, assignment to a particular area of Vietnam influenced the amount of combat exposure immensely; newly won areas often entailed more combat than areas of established strength. However, it is also very plausible that personal qualities had their strongest impact on decisions made in the actual field of battle.

Company commanders survived by selecting those soldiers whose personal characteristics yielded successful combat outcomes within Vietnam's specific environment. Leaders may have exposed certain individuals to high-risk combat assignments because they demonstrated behaviors that would increase the probability of victory or safety. Much like mid-level managers within a large corporation, the interests of company commanders focused on immediate accomplishment, in contrast to the higher-level executives (away from the battlefield) whose concerns are the long-term functioning of the larger organization (Scott 1981).

While a potential combatant should certainly be highly disciplined, confidence, determination, aggression, and boldness are also essential to the military mission (Bryant 1979). Individuals willing to take a certain amount of risk who were aggressive and did well under stress would have been desirable as combat soldiers. Therefore, according to the potential combatant model, individuals with these characteristics would have been exposed to more combat than soldiers without these characteristics.

We examine several indicators of aggressiveness and stress management: testosterone levels, cortisol levels, antisocial behavior in schools, and antisocial behavior in the military. Testosterone level is a useful indicator of aggressive tendencies. A number of studies have demonstrated a consistent and moderately strong relationship between testosterone and aggression in youth and adults

(e.g., Christiansen & Knussmann 1987; Ehrenkranz, Bliss & Sheard 1974; Olweus et al. 1980), antisocial behavior such as fighting, nontraffic arrests, and drug use in adults (Dabbs & Morris 1990), juvenile delinquency and adult deviance (Booth & Osgood 1993), and sensation-seeking (Daitzman & Zuckerman 1980. Testosterone has been shown to be stable over time, with reliabilities ranging from .50 to .65 for measures taken in the span of one day and up to six years apart (Dabbs 1990; Gutai et al. 1990). Therefore, if our models are correct, basal testosterone levels obtained long after combat should predict an increase in combat exposure.[2]

We draw on another biosocial variable, cortisol, as an indicator of ability to handle stress. While often studied as a response to stress (Henry 1992; Sapolsky 1992), basal levels of cortisol indicate an aptitude for dealing with stress. For example, research has shown that the most consistently successful competitors have lower cortisol levels. These individuals remain cool in times of intense competition (Booth et al. 1989) and are predisposed to handle stress well. This quality appears early in life. Kagan, Reznick, and Snidman (1988) have shown that the propensity to handle unfamiliar situations and engage other individuals appears in youngsters age seven and under and is related to low cortisol production. Research on soldiers in high-stress assignments in Vietnam (Green Berets and helicopter ambulance pilots) also shows uniformly low cortisol levels (Bourne, Rose & Mason 1967, 1968). Thus, men predisposed to handle high-stress situations well would have been more desirable in the high-stress atmosphere of battle and would have received appropriate assignments.

Once behavioral indicators of aggressiveness and the ability to handle stress are taken into account, the biological indicators should recede into the background. Unfortunately for purposes of this analysis, we only have two behavioral indicators of aggression. One is a premilitary indicator of aggressiveness and risk-taking in school. The second is an indicator of disciplinary problems while in the military.

We view the risk-taking, aggressiveness, and stress-handling behavior as factors that affect decision making about combat duty by those making daily field assignments. Our third hypothesis follows from these considerations:

Hypothesis 3. Higher testosterone levels, lower cortisol levels, more school problems, and problem behavior in the military increased levels of combat exposure when controlling for combat arms assignment.

Support for the third hypothesis would indicate that the potential combatant model holds for the last phase of the decision process. However, given the risks associated with combat, the potential support staff model may also be valid at this stage. A tactic used in Vietnam was to have ground troops move into positions that would draw the enemy out, i.e., using them as bait (Helmer 1974); once exposed, artillery and tactical aircraft were brought in to destroy the enemy. It was believed this could be a viable tactic because of the capability to deploy sophisticated medical support rapidly to treat battle injuries. Yet, the inherent danger of this tactic was still great enough that the Army probably continued to assign those who could not fill more technically demanding support slots to combat activity. Hence, our fourth hypothesis:

Hypothesis 4: Having a low aptitude, being drafted, and being less than 19 years of age at entry into the military increased levels of combat exposure when controlling for combat arms assignment.

RACE

The role of race is examined in each phase of the process from induction to combat. Race could have been a discriminatory factor in any of the assignments. However, it is important to note that most research neither supports the notion of disproportionate African-American service during the Vietnam War (Berryman 1988; Card 1983; Fligstein 1980; Kulka et al. 1990), nor the idea that African-Americans had higher levels of combat exposure (Card 1983; Frey-Wouters & Laufer 1986) or higher casualty rates (Badillo & Curry 1976). In fact, of the major studies encompassing information from all or most of the war years, only Card (1983) finds any sign of racial differences in service: a higher proportion of nonwhites than whites in the ground forces. This difference did not result in differing levels of combat exposure for whites and nonwhites.

These findings do not support those reported early in the war by the popular press (Binkin et al. 1982) and by Moskos (1970) using U.S. Department of Defense data for war years through 1968. Casualty rates suggest that beliefs about disproportionate minority involvement may have been true early in the war but that the proportion of African-American casualty rates declined over time (Appy 1993). Although later research does not support these early conclusions, the belief lingers that a greater than expected number of nonwhite men fought in Vietnam; therefore, it must be retested continually using different data and different models. Thus, the conflict between research and public opinion leads to our fifth hypothesis:

Hypothesis 5. Race was not a significant factor in receiving a combat arms occupational assignment, being sent to Vietnam, or receiving combat exposure.

PERIOD OF THE WAR

Thus far, our arguments imply that the Army was a closed system in which all decisions were driven by internal imperatives (Scott 1981). While the U.S. was present in Vietnam, dramatic changes occurred in the level of American involvement, wartime goals, and public opinion (Krepinevich 1986). It seems unrealistic to suggest that the changing external environment would have no impact on the selection of men for combat. However, no broad changes in Army strategy during the Vietnam War were made in response to the war's negative progress. By 1968, when it was apparent that conventional strategies were not successful, American policy already had switched to withdrawal rather than victory (Krepinevich 1986). Thus, as the war progressed differences would not be expected in soldiers' assignment to the combat arms or to Vietnam since such changes would reflect overt policy changes at an organizational level. However, the impact of the changing external environment both in the U.S. and on the battlefield was probably more noticeable at the company level where lessons learned in combat and subtle shifts in wartime goals could be translated more easily into action.[3] Early in the war when victory rather than withdrawal was the

goal, an effort might have been made to utilize soldiers whose personal characteristics made them better combatants regardless of their other skills or potential. In fact, prior to the Vietnam War an effort was made to channel low aptitude men away from combat assignments. (See Moskos [1973] for a discussion of this policy as applied to the integration of the Army.) Once ultimate withdrawal became the goal, the potential support staff model, which served to keep talented men away from battle, may have been implemented over the potential combatant model. These considerations concerning period of the war lead to our sixth hypothesis:

Hypothesis 6. Factors that enhance combat desirability (testosterone, cortisol, school problems, behavior problems in the military) will be stronger predictors of combat exposure prior to 1968 than in 1968 and after. Factors that decrease desirability as support staff (low AFQT scores, drafted, young at entry) will be stronger predictors of combat exposure in 1968 or later than they are prior to 1968.

Research Procedures

THE SAMPLE

The sample is composed of men who served in the Army between 1965 and 1971. There are no officers and the men performed only one term of service. The men were randomly selected from military records of all nonofficers who served in the Army from 1965 to 1971. They were a part of a Congressionally mandated study of the long-term psychological and physical consequences of service in Vietnam conducted by the Centers for Disease Control (CDC 1989a). The men were medically and psychologically examined between June 1985 and September 1986. Sixty percent of those selected took part in the study. The most common reason for refusal to participate in the extensive examinations was work-related (CDC 1989a). When those who participated are compared to those selected for study, we see only small differences in the two groups. Eighty-seven percent of the selected Vietnam veterans were white, while 82% of those who actually took part in the study were white. Twenty-six percent of those selected fell into the lowest category of the enlistment technical test, while 23% of the participant were in this category. No more than two percentage points separated those who participated from those who were selected with respect to the distribution on age at entry, whether they were drafted, tactical military specialty, other categories of the enlistment technical test, year of entry, pay grade at discharge, and honorable discharge. The modal difference is 1% (CDC 1989). While this sample does not permit conclusions about other branches of the military, officers, and those who did not survive or reenlist, it is representative of those who served in the Army, which is the largest service.

The first analyses were conducted on 4,338 of the examination participants who had no missing data. Because the sample overrepresented those who went to Vietnam, the data were weighted to achieve the proportion (21%) of personnel in Vietnam during July 1968 (Department of the Army 1968). Our second set of analyses were conducted on 2,389 of the participants who actually served in Vietnam.

These data do not allow us to examine the full range of soldiers who entered the Army and went to Vietnam. The respondents are selected for having survived the war and the ensuing years of peace. This concern is especially germane to the case of African-American soldiers. As discussed previously, early in the war race was a factor in combat deaths. However, for the entire war, "black casualties were only slightly disproportionate (12.5 percent from a population of 11 percent)" (Appy 1993:19). Thus, we may underestimate the effects of race in the course of our analyses but given the changes in proportion of African-American casualties over time, the bias, if any, will be quite small.

MEASUREMENT

Dependent Variables

Combat Arms Assignment is an occupational specialty to which the individual was assigned and not the organizational unit in which they were placed. Jobs included in the combat arms assignment are infantry, combat engineers, field artillery, and air defense artillery. It is represented as an indicator variable coded 1 if men were assigned to a combat arms position and 0 otherwise. Vietnam Assignment is represented as an indicator variable coded 1 if the men served in Vietnam and 0 otherwise.

Combat exposure is represented using a variable computed as the total score summed over 12 items with scores ranging from 0 to 4: 0 = never had the experience, 1 = rarely, 2 = sometimes, 3 = often, and 4 = very often. The range for this variable is 0 to 48. The items are:

(1) Part of a land or naval artillery unit that fired on the enemy;
(2) Flew aircraft over South or North Vietnam;
(3) Stationed at a forward observation post;
(4) Received incoming fire;
(5) Encountered mines and booby traps;
(6) Received sniper or sapper fire;[4]
(7) Unit patrol was ambushed;
(8) Engaged Vietcong in firefight;
(9) Engaged North Vietnamese Army in firefight;
(10) Saw Americans killed or injured;
(11) Saw Vietnamese killed or injured; and
(12) Killed someone or thought had killed someone.

Principal factor analysis indicates that this is a unidimensional scale with an alpha coefficient of .92.[5]

Biosocial Factors

Biosocial factors used are the hormone levels for testosterone and cortisol. Testosterone and cortisol concentrations were assayed from single serum samples collected at 8:00 a.m., before breakfast. A standard double-antibody radioimmunoassay was employed (CDC 1989b). For the weighted subsample of Vietnam-era veterans, testosterone levels ranged from 53 to 1,950 nanograms/deciliter. For the same group, the range of cortisol levels was 3.7 to 48 micrograms/deciliter.

Background Factors

Race is a dichotomous variable coded 1 for African Americans and 0 for all others.[6] We measure intelligence/aptitude using the men's scores on the Armed Forces Qualifying Test (AFQT), which is administered at the time of entry into the military. AFQT scores are categorized into four levels with 1 indicating the lowest scores on the test and 4 indicating the highest.[7]

School Problems

We use a four-item index composed of misbehaving in school, expelled or suspended from school, playing hooky, and fighting at school. Principal components analysis indicates that it is a unidimensional scale with an alpha coefficient of .60 and ranges from 4 to 8.

Military History

Three indicators of military history were used: age at entry, method of entry (draft or volunteer), and whether the men had behavior problems while in the military. A 1 for the respective variables represents age 19 or younger when entering the military, entry by the draft, and being absent without leave (AWOL) or confined while in the military.[8]

Method of Analysis

Weighted logistic regression is used to estimate the probability of receiving a combat arms assignment and assignment to Vietnam. Ordinary least squares regression is used to estimate the models of combat exposure. For consistency, in each model we test for the main effects of biosocial factors, background factors, school problems, and military history variables. For combat exposure, we estimate a series of five models entering blocks of variables one at a time: biosocial, background factors, school problems, military history, and combat arms assignment.

Findings

Zero order correlations, means, and standard deviations for variables used in these analyses can be found in Table 1. The majority of bivariate relations are in directions consistent with our hypotheses. The relationships between combat arms assignment and AFQT score, age at entry, and being drafted are all in the direction expected as are those between Vietnam assignment and AFQT score and age at entry. Similarly, the correlations for combat exposure are in expected directions.

With respect to race, no statistically significant relationship exists between race and combat arms assignment or being sent to Vietnam. However, a statistically significant positive bivariate relationship exists between race and combat exposure.

COMBAT ARMS ASSIGNMENTS

When combat arms assignment is regressed on biosocial factors, background factors, school problems, and military history characteristics, the expected independent relationships emerge (Column 1, Table 2). The negative statistically significant relationship between AFQT score and combat arms assignment indicates that the probability of receiving a combat arms assignment increased by 21% with every quartile decrease in AFQT score, controlling for the effect of all other variables in the model. Entering the military under the age of 20 and being drafted also increased the probability of receiving combat arms assignments.

One unexpected finding emerged: testosterone has a positive effect on the probability of assignment to a combat arms position. This is surprising because it is not clear how Army decision makers could have information on testosterone or on related aggressiveness and risk-taking. The finding is also suspect because the testosterone-combat arms assignment coefficient is not influenced by the relevant behavioral measures of aggression. It is also a very small effect when

TABLE 2: Logistic Regression Coefficients of Combat Assignment and Vietnam Regressed on Biological Factors, Pre-Military Problems, and Military Factors While Controlling for Race and Intelligence[a]

	Combat Arms		Vietnam	
	Coef.	S.E.	Coef.	S.E.

Pseudo R^2	.02		.01	
(N=4,338)				

[a] Data are weighted to yield .21 in Vietnam.

* $p < .05$ ** $p < .01$

or on related aggressiveness and risk-taking. The finding is also suspect because the testosterone-combat arms assignment coefficient is not influenced by the relevant behavioral measures of aggression. It is also a very small effect when compared to the size of the other significant coefficients in the model. There is only a 7% increase in probability of combat arms assignment for every standard deviation increase in testosterone level.

Despite this one unexpected finding, our first hypothesis is supported. Combat arms assignments were made primarily on the basis of factors indexing ability to perform noncombat support jobs (AFQT scores and age at entry) and long-term commitment to the military (draft).

ASSIGNMENT TO VIETNAM

When Vietnam assignment is regressed on biosocial factors, background factors, school problems, military history characteristics, and combat arms assignment, two of the expected main effect relationships emerge (Table 2, column 2). Low AFQT scores and obtaining a combat arms assignment each increase the probability of assignment to Vietnam. However, age at entry and draft have no effect, suggesting that more subjective inferences concerning maturity and commitment may not have played as great a role in assignment to Vietnam as other less subjective indicators.

The fact that the coefficient for being drafted is negative (although nonsignificant) is especially puzzling. Because the effect of draft on being sent to Vietnam may differ depending on combat arms assignment, we tested an interaction term between draft and combat arms assignment in our model and found it to be positive and statistically significant (analyses not shown). This indicates that being drafted and assigned to a combat arms job increased a soldier's probability of being assigned to Vietnam. In fact, further examination of the differences in probability of service for the four groups implied by the interaction term (drafted with combat arms assignment, volunteered with combat arms assignment, drafted with other assignment, and volunteered with other assignment) indicates that draftees with combat arms assignments were more likely to be sent to Vietnam than were draftees without such assignments, volunteers with combat arms assignments, and volunteers with other assignments. Being drafted did not mean automatic assignment to Vietnam but being drafted and assigned to combat arms placed men at great risk of this destination. To summarize, we find support for the potential support staff model because men with lower AFQT scores, combat arms assignments, and draftees with combat arms assignments were more likely to be sent to Vietnam. However, neither age at entry nor simple draft status seemed to play the expected part in this analysis.

COMBAT EXPOSURE

Combat exposure regressed on the biosocial factors reflects the relationships predicted by the potential combatant model (Table 3, column 1). Higher levels of testosterone are associated with greater combat exposure and lower levels of cortisol are associated with higher levels of combat exposure. The relationship between cortisol and combat exposure holds when the background factors of race and AFQT score are added into the model. The relationship between testosterone and combat exposure is only moderated slightly when the background factors are entered although it is no longer statistically significant (Table 3, column 2).

As expected in a multivariate model, race has no significant effect. The bivariate relationship between race and combat is accounted for by AFQT scores. The coefficient for AFQT score is significant and negative as expected, indicating that lower AFQT scores are associated with higher combat exposure. The fact that AFQT scores account for the bivariate relationship between race and combat exposure suggests that race alone was not a factor in exposing soldiers to

combat. However, it is possible that race modified the effect of AFQT. That is, African Americans who scored low on this aptitude test may have experienced greater combat exposure than whites with low scores. We tested this possibility by creating a race-by-AFQT interaction term and entering it into the equation. It was not statistically significant ($p = .29$).

When the school problems indicator is added to the model, the coefficient for testosterone is reduced dramatically (by 50%), but the cortisol coefficient is only reduced slightly. As these biosocial variables reflect predispositions to behavior, we expect them to recede in importance once the behavioral indicators are added to the equation. Clearly, school problems is a behavioral indicator of different levels of aggressiveness. Since direct behavioral indicators of pre-military ability to handle stress were not available in this study, the fact that the cortisol coefficient is not appreciably affected by the addition of the pre-military problems variable is not surprising. The coefficient for AFQT remains negative and significant.

Adding the military history variables (young at entry, drafted, and problem behavior while in the military) does not appreciably affect the coefficients for biosocial factors, background factors, or antisocial behavior in school. As expected, each of the military history variables has a significant effect on level of combat, independently contributing to the exposure level.

Adding combat arms assignment to the model causes two important changes: it adds considerably to the power of the model, increasing the R^2 from .06 to .29; and the coefficient for drafted drops from .09 to -.04. This suggests that once the effect of assignment on level of combat exposure is removed, draftees sent to Vietnam actually experienced slightly less combat than volunteers sent to Vietnam. It is important to note that even with combat arms in the model the coefficient for AFQT remains negative and significant.

TIMING OF SERVICE

Finally, understanding the combat process requires determining the nature of the interaction between the period of the war and individual characteristics, and the effect of this interaction on risk of combat exposure. Those who went to Vietnam were divided into cohorts based on initial date of Vietnam tour. In separate models, we test interaction terms formed by multiplying early service (1965-1967) and each of the model indicators: testosterone, cortisol, antisocial behavior in school, disciplined in the military, AFQT score, young age at entry, and drafted (analyses not shown). A significant negative interaction term was found for young, early Vietnam assignees and a significant positive term for the interaction between early service and AFQT scores. Among those who went to Vietnam early in the war, being young is associated with a decrease in combat score. In addition, the inverse relationship between AFQT scores and combat scores is not as strong for those in Vietnam in the early years as it is for those who went later on. These significant interaction terms demonstrate some changes in the conduct of the war depending on the war period. On the battlefield, the potential support staff model does not fit behavior early in the war as well as it fits behavior that occurred later when winning the war was out of the question.

Discussion and Conclusions

Using a sample of 4,338 surviving Army nonofficers who served one term during the Vietnam conflict, the main effects of biosocial characteristics, background factors, antisocial behavior in school, and military history on (1) risk of combat arms assignment, (2) risk of assignment to Vietnam, and (3) level of combat exposure once in Vietnam were examined. Combat arms assignments were made primarily on the basis of factors that indexed ability to perform noncombat support jobs (AFQT scores and age at entry) and long-term commitment to the military (volunteered). Assignment to Vietnam depended on job assignment. In addition, a low AFQT score increased the probability of service in Vietnam; for draftees, a combat arms assignment further enhanced the probability of going to Vietnam. For the first two stages of the selection process, the analyses suggest that an individual's risk of combat was determined by his ability to perform jobs other than combat, i.e., support staff tasks. Moreover, even after occupational and locational assignments were made, the potential support staff model continued to operate, thereby influencing the level of combat exposure. Men serving in Vietnam with low AFQT scores and who were young at entry were more likely to see combat even when controlling for assignment. However, the potential combatant model also contributes to the explanation of combat exposure. Those who were aggressive and had good stress management skills were more likely to experience combat. Level of combat exposure was also somewhat influenced by whether the war was considered winnable. Those who had strong potential for support staff positions experienced more combat in the early stages than in the late stages of the Vietnam War.

In addition, our results support previous findings that racial differences did not exist in assignment or in combat. The role of race was examined for all three dependent variables. We find no direct effects of race on combat arms assignments, Vietnam assignment, or level of combat exposure. In addition, we find no indication of differing treatment for African Americans and whites based on AFQT score. However, given the importance of AFQT to our models and the significant negative bivariate correlation between race and AFQT we must consider institutional or nonpurposive discrimination as an alternate explanation for these findings. If African Americans were more likely to have low AFQT scores than whites, they also were more likely to see combat. Unfortunately, our data do not allow us to adequately develop multivariate models that predict AFQT score as an early stage in the process leading to combat. Our data also do not allow us to look at two other crucial aspects of the relationship between race and the Vietnam War: entry into the military as a dependent variable and socioeconomic status as a predictor variable. Examination of issues related to entry into the military would add to our understanding of the relationship between race and service in Vietnam by dealing with both issues relating to service avoidance and disproportionate rejection of certain groups because of low aptitude scores. (See Baskir & Strauss [1979] for a discussion of service avoidance and Segal [1989] for a discussion of low aptitude rejections.) As indicated by other research (e.g., Appy 1993), examination of socioeconomic

status as a predictor of combat-related experiences would add to our understanding of the links among combat, race and AFQT scores.

One variable in our analyses acted in an interesting way. While the relationship between behavior problems in the military and combat exposure is as predicted by the potential combatant model, the relationship between testosterone and behavior problems in the military in the combat exposure models suggests that our indicator of behavior problems in the military is not an indicator of aggressive behavior. Entering this variable into the regression equation does not mediate the relationship between testosterone and combat exposure or the relationship between antisocial behavior in school and combat exposure. This leads us to suspect that this indicator would better fit within the potential support staff model. One indication that individuals may be appropriate for support staff is their lack of behavioral problems while in the military. Being AWOL or in confinement appears not to indicate an aggressive person but perhaps to indicate a person who has problems with the authority structure of the military, an indicator of low potential for military success. Increased combat exposure for these problem GIs also could have been a form of punishment for past performance.

We also believe that our models, in general, may have portrayed these men as passive characters whose every movement within in the military is decided by others. This is not the case. The men were also actors who in many ways shaped their own destinies. Some soldiers may have reenlisted to avoid assignment to Vietnam as we pointed out earlier (Baskir & Strauss 1978). Others may have used presentation and negotiation skills to avoid combat once in Vietnam. Baskir and Strauss (1978) provide an illustrative example:

> In all, a soldier had a better-than-even chance of getting an assignment away from the search-and-destroy missions and other field operations. Anyone who made a good impression had a good chance of staying out of combat. As Pat Brannigan, now a career Army officer, recalled: "When I landed, I talked about computers to anyone who would listen. I knew that computers were always kept air-conditioned and far from combat areas. As it turned out that's how I spent my year." (59)

(See also Curry [1985] for a discussion of manipulation of the military personnel system.)

Through their own actions, individuals also may have become involved in situations that carried a high risk of combat in order to attain a sense of control (Appy 1990) or a psychological high (Appy 1990), or because of the opportunity to perform and be rewarded for skill and proficiency by receiving admiration from others (Appy 1990). Moreover, those with higher testosterone may have been predisposed to seek combat as an extension of their hormone-driven impulses. A feedback loop may have existed in which the performance decisions of individual soldiers fed into the decisions of those making daily combat assignments. The officer's decision to make further combat assignments then reinforced the individual's predilection to engage in combat. Unfortunately, our current data do not permit us to assess whether these experiences stemmed from individuals either acting or being acted upon, or some combination of the two.

These analyses make several contributions to our knowledge of the Vietnam experience. First, in our treatment of the determination of combat exposure as

a multiphase process, we have studied the importance of soldier characteristics at each. Intelligence and aptitude appear to be important factors in determining combat exposure at each stage of the process. There is a significant negative relationship between AFQT score and combat exposure for men who served in Vietnam even when controlling for the effect of AFQT score on combat arms assignment; this strongly supports the idea that even in the theater of war, the field of combat was the site for men not suited to other tasks. Our findings suggest that the decision-making strategies across all three phases of the process were the same. Previous research indicated the importance of intelligence/aptitude in this process but did not reveal its importance at each stage of the decision-making process.

Second, previously unidentified groups of men have been distinguished as having been at heightened risk for combat-related occupational assignment, assignment to Vietnam, and beyond that, actual combat exposure. The first group contains those not suitable for the training provided by military service, as indexed by aptitude/intelligence scores, draft status, and age at entry. The importance of aptitude scores in determining ultimate risk of combat exposure is profound, but the other status characteristics also play a role. The fact that this group had a heightened risk of combat exposure may provide an example of discriminatory results that were not rooted in prejudicial attitudes or purposely discriminatory behavior.

Another previously unidentified group is men with biosocial predispositions to aggressive behavior or good stress management. By identifying the importance of these characteristics in determining the level of combat exposure, we gain insight into the role of biosocial predispositions in social situations and into the way in which more personal characteristics may have determined an individual's risk of combat exposure. Our results suggest that while the decision-making process at the battlefield level was similar with regard to status characteristics, it was very different in its focus on men who could get the job done rather than on placing men in combat who could not do other jobs.

Third, the risks to the least advantaged soldiers appeared to increase when the battle was defined as lost. Despite efforts in 1967 and 1969 to reform the draft and thus democratize service in Vietnam (Appy 1993), this research provides evidence for a differential impact of personal characteristics on combat exposure depending on the time period of the war. We provide empirical support for the idea that talented men were channeled away from battle in the later years of the war. The declining overall support for the war appears to have influenced not only the number and location of soldiers who entered combat, but also the type of soldiers who actually fought.

Finally, our identification of the importance of status characteristics and biosocial factors in determining the ultimate level of combat exposure may help to explain why some individuals had problems following combat and others did not. The least able combatants may have suffered more distress after the war than those with biosocial predispositions to aggressive behavior or good stress management. The ability of the least able to deal with the aftermath of combat may have been severely hampered by the very lack of social and intellectual resources that brought them to combat. On the other hand, the combat-able or perhaps even combat-seeking soldier may have negotiated the combat experience

with less psychological trauma as a result of temperament or skills that may have made him a better combatant or combat-seeker. This temperament or these predispositions may have made combat a less stressful experience for him.

Further research in this area should focus on sorting out the reasons for the suffering experienced long after a war by some men and not by others and for the varying magnitudes of these problems. We believe that a focus on pre-military characteristics and experiences may provide part of the answer. First, biosocial predispositions may serve as protective factors against the trauma of combat. Second, the pathways from pre-military characteristics and experiences to later-life problems may be both direct and indirect through combat. Future research should focus on clarifying these paths. Understanding these relationships could have policy implications both for selection of individuals for future combat situations and for the care for those who return.

Notes

1. A support assignment did not prevent individuals from experiencing combat. For example, if someone with a service support position was located in an area overrun by the enemy, that individual was likely to be engaged in combat.

2. A full exploration of the role of testosterone in increased combat exposure must consider the possibility that basal levels of testosterone are the result, not the cause, of behavior (Kemper 1990). Extraordinary daily competitive pressures may result in higher basal levels of testosterone. Thus, it might be argued that repeated combat experiences might lead to higher basal testosterone levels even years after combat. However, studies of varsity tennis, wrestling, and community-level chess competition do not support this (Booth et al. 1989; Mazur et al. 1991). Even over the course of a season, postcompetition testosterone levels always return to precompetitive levels. There was no sign of a gradual increase, even among the most successful players. It is also possible that some men who served in combat found the risk very exciting (Appy 1990) and continued after the war to seek out high-risk activities to recreate this psychological high. These continued high-risk behaviors could possibly result in later-life elevated testosterone.

3. See Krepinevich (1986) with respect to counterinsurgency tactics.

4. A sapper is a soldier who tries to infiltrate a base or camp to destroy lives or property (Baker 1981).

5. This self-report combat experience measure comes from the Legacies of Vietnam Study (Centers for Disease Control 1988).

6. Analyses including indicator variables for white, African-American, Hispanic, and Native American yield nonsignificant coefficients for all subgroups. For reasons of parsimony, only the African-American indicator variable remains in the equation.

7. While AFQT scores are typically reported in categorical form, this form of coding for AFQT scores is not usually used. Typically, these scores are reported as five categories with the highest aptitude soldiers in category 1 (i.e., Laurence & Ramsberger 1991). For our analyses, the two lowest categories were collapsed into one because of low frequencies in category 5. Then we reversed the coding so that it would be appear logical to those unfamiliar with traditional methods of AFQT reporting.

8. Confinement was one form of nonjudicial punishment that could be ordered by local commanders in response to minor offenses against the Code of Military Justice or in response to violations of other military rules (Bryant 1979:30).

The Toggle Switch of Institutions: Religion and Art in the U.S. in the Nineteenth and Early Twentieth Centuries*

JUDITH R. BLAU, *University of North Carolina at Chapel Hill*

Abstract

An institution is taken for granted when it is enveloped within a cultural and moral framework that is not contested. The usual account of the institution of high culture that emerged in the U.S. in the late nineteenth century relates to the growing importance of elites and the uncertainties of modernization. This raises an important puzzle: how did the visual arts that had been so dominated by the morality of popular religion acquire secular worth? Weber's writings provide a point of departure for analyzing institutional transformations involving art, religion, and the emergence of the avant-garde. A framework for understanding institutional change is sketched out. It includes the importance of ideology, social and economic interests, and intellectuals who articulate emerging new views. The metaphor of the "toggle switch," adapted from Weber's term, switchmen, captures the idea that transformation occurs when there are underlying cultural contradictions and the resolution of these contradictions depend on the investments and prospects of competing interests.

A prevailing view of art is that it is part and parcel of culture, and, as such, has a functional relationship with a set of values that underlies social life and large-scale institutions. Art, according to this view, exhibits considerable inertia. It does so because its development and legitimation are profoundly implicated in group life (Becker 1982), social class (Bourdieu 1984; Gans 1974), organizations (Blau 1989; Peterson 1976), or elite interests (DiMaggio 1982).

This perspective is consistent with institutional theory, which emphasizes that culture, generally, has a high degree of coherence and consistency (Parsons

* *This work accompanies quantitative research on the transformation of cultural institutions supported by the National Science Foundation (SES-9108923). Early versions of this article were presented and discussed at the annual meetings of the Fourth National Sociology Conference in Norway (1993), at Pennsylvania State University (1994), and at Vanderbilt University (1994). For their generous and helpful suggestions I thank Arild Danielsen, Jennifer Glanville, Richard Peterson, Alan Sica, Joseph Soares, Jonathan Turner, and an astute anonymous reviewer.* *Direct correspondence to Judith R. Blau, Sociology Department, University of North Carolina, Chapel Hill, NC 27599-3210.*

1951), is interwoven with social arrangements that are keyed by rules (DiMaggio & Powell 1983), and that group and symbolic boundaries are defined in terms of one another (Bourdieu 1991; Douglas 1986; Lamont 1992). In other words, there are functional relationships and congruences between culture and the social order, whether culture operates from the top down (Douglas 1986) or the bottom up (Becker 1982), whether it fosters social order (Parsons 1951) or is oppressive (DiMaggio & Powell 1983).

The difficulties with the conception of art as coherent with the social order is that elements of a taken-for-granted institution can be antithetical to one another. Because legitimation entails great tenacity of investments and interests, institutional contradictions often remain obscure while embodying potential for significant transformation. The present article is a case study of the dislocations between religion and art in the U.S. in the nineteenth century, and I pose the problem of how secular art became autonomous after decades of being subordinate to popular religion.

To account for the mechanism of institutional transformation, I draw on Weber's (1946b) metaphor of the "switchmen" (280) ("Weichensteller der Bahnen"; Weber 1920:252) of social change. According to Weber, the switchmen that alter the direction of social change involve "world images" that are created by ideas and are driven by interests. Elsewhere, he suggests that the switching is triggered by deep-seated cultural contradictions. Weber ([1930] 1976) traced cultural (religious) beliefs to the "needs" or the interests of particular groups, but intellectuals, the bearers of rational culture, play particularly important roles. Moreover, he suggests that art can function much as traditional religion does; that is, through its subjectivism, art provides an escape from the very disenchantment that rationalization and science produces (Weber 1968,1:607-10). Weber's writings on the relations between art and religion, and the role of intellectuals in social change, are sketchy at best, but in this case study of the Arnoldian movement in America, it is possible to provide an empirical account of the transformations in the relations between religion and art in the U.S. and in the way that intellectuals provided a language that led to the subsequent development of the avant-garde.

The basic assumptions that can be gleaned from Weber's writings are the following: (1) that ideas and worldviews have considerable autonomy and are consequential (Weber 1946a, [1930] 1976); (2) that worldviews have their origins in socioeconomic conditions because groups have different interests (Weber 1946a; also see Bourdieu 1984; Sadri 1995); (3) that there are critical moments when the contradictions among worldviews can most powerfully motivate social change, as Weber's (1946b) "switchmen" metaphor suggests; (4) that art, which emergences as a potent force under conditions of rationalization, competes with salvation religion (Weber 1946a, 1968, 1); and (5) that intellectuals acquire unusual visibility and persuasiveness during periods of great flux (see especially Sadri 1995; also see Swidler 1973).

Further Considerations: The Toggling of Institutional Change

Weber's own metaphor, "switchmen," implies a mechanism that simply alters the direction of change, and it is inconsistent with his insights about the conditions of cultural contradiction. I use instead the "toggle switch" as an apt metaphor. The toggle translates one small input into a far larger effect, and this effect is indirect and often not obvious. In this sense, the toggle imagery captures the complex instrumentalities of historical change and problematizes the character of change.

Some of the inconsistencies and vagueness in Weber's arguments can be resolved by explicitly using the concept of ideology (Bourdieu 1991), specifically that differences in interests and status express themselves in discourse, representation, and social space. In this way we can begin to unpack the conditions under which institutions acquire a taken-for-grantedness, to suggest that they do so in terms of ideology, and also to suggest that taken-for-grantedness masks strategies of containment (Jameson 1981) and conceals from participants their variances and contingencies (Adorno 1973).

This case study suggests that art and religion "and, by extension, other domains of culture" have themselves transformative relations that are not completely reducible to groups, classes, and organizations, but rely on them, as interests are expressed in ideological terms (Eagleton 1991; Tarrow 1994; Touraine 1988), and are embedded within the expansive worldviews provided by science, theology, and philosophy.

I shall argue that the prevailing ideology of salvation religion during the nineteenth century was pervasive, as it was highly compatible with economic liberalism (Weber [1930] 1976) and dictated the character of nation building (as evident, for example, in school and reform movements) and the rules for acceptable social behavior. Yet the high culture movement that was so antagonistic to popular religion drew on social Darwinism to legitimize social and economic hierarchies, and to be legitimized by them. A practical instrument for this transformation in cultural institutions was the Arnoldian movement in the 1880s and 1890s, successful perhaps, in part, because of the fact that Matthew Arnold was a credentialed foreign (that is, exotic) intellectual, but also because he appealed to class and status interests as he defended both the high culture movement and social Darwinism. This is not to credit Arnold with this important transformation, but rather to consider the Arnoldian movement as providing clarity for the articulation of emergent conceptions about religion and art in the social order.

High Culture and Elite Sponsorship: The Conventional Account

The prevailing interpretation of the emergence of the fine arts in America at the end of the nineteenth century is that elites drew on the distinction between popular and high culture to bolster class differences (Archer & Blau 1993; Blau 1991; DiMaggio 1982; Horowitz 1976; McCarthy 1982; Miller 1966; Minihan 1977).

At the end of the century, the entrepreneurs of high culture responded to the destabilizing effects of immigration, vice, pauperism, and industrialization while providing forms of class security for the middle class and opportunities of ostentatious display for the urban rich. As Trachtenberg (1982) notes, "Changes in social structure, the polarization of rich and poor and the growth of a salaried middle class anxious about its own status opened the opportunity — indeed, created the necessity — for the healing properties identified with high culture" (145).

Exclusionary symbols helped to map the terrain (Whitehall 1970), while the rejection of (vulgar) popular culture provided reassurance of "good taste," elegance, and distinction (Bourdieu 1984; Lamont 1992; Slater 1976). Also accompanying this account of elite sponsorship is an analysis of the organizational means by which art would be sacralized. Such organizations as museums and orchestra halls contributed to the institutionalization of high art, for without fashionable public arenas, claims to superior taste were suspect as being snobbish, trivial, and undemocratic (DiMaggio 1992; Hall 1984; Wiebe 1967).

DIFFICULTIES IN THE CONVENTIONAL ACCOUNT OF HIGH CULTURE

This interpretation of the role of elites and organizations in the development of high culture is misleading for the U.S. because it misspecifies the relations between religion and popular culture and ignores how the fine arts were defined in America throughout the nineteenth century. To be sure, the performing arts and, to some extent, literature, were thoroughly integrated into secular leisure (Barth 1980; Cmiel 1990; Kasson 1990; Levine 1988; Toll 1976). Levine (1988), for example, demonstrates that what was later considered to be high culture, such as Shakespearean plays and Italian operas, were widely popular and enjoyed along with vaudeville and fairs. However, this is not the case for the visual arts, which were bracketed through most of the nineteenth century and were governed by religious norms (Commager 1950; May 1976; Miller 1965; Perry 1989). Popular culture "entertainment" could be contained (Jameson 1981) within an ideological order of austerity, asceticism, and piety because entertainment did not constitute a worldview with potent moral meaning (Shi 1985).

Religious traditions had a secure hold on art, and legitimization of the visual arts, independent of religion, required an effective displacement from the rhetoric of religious morality to the rhetoric of aesthetic value. If there was a drift away from religious morality and asceticism at mid-century, the Civil War brought a renewed celebration of piety, spartanism, and the denunciation of effeminate and indulgent practices (Shi 1985).

Rapid industrialization after the war spurred increasing differentiation between city life and rural life and growing economic disparities between workers and owners as well as between the affluent elite and the growing middle classes. It was later, around the 1880s, that the number of immigrants expanded dramatically, and, at least as important, their origins were no longer from predominantly, or even largely, Protestant nations. Increasingly, status rested less on behavior that could be observed in communities, and more on secular and universalizing conceptions of worth, such as education, life-style, and wealth (for this general point, see Lockwood 1992:87-93).

Thus, economic elites, under the conditions of growing inequalities, played a major role in creating the conditions for the development of high culture in America. Yet the connections between religion and art had to be severed for high culture to emerge. These antithetical relations were deeply rooted in a particular conception of morality, and high art required ideological justification.

Normal Morality and American Exceptionalism

The nineteenth-century American bourgeois shared with their northern European counterparts deep mistrust of sexuality, sin, and evil. The Victorian sensibility "defined itself largely through its fixation on the dangers of desire" and through its at least nominal adherence to a code of "earnestness and self-denial" (Herbert 1991:30). This sensibility, according to Gay (1986), reflected a great preoccupation about the line between the pure and the impure. In America, the distinctions were amplified at the pulpit and in the Sunday school and sectarian conceptions of morality played an important role in people's lives. Yet a major contrast is that in America these lines were drawn around religious and ethnic differences, whereas in Europe class differences played the more important role.

Lacking a class framework for moral evaluations, religious differences were the dominant ones, and these were fine-tuned as the difference between evangelical denominations — Methodists, Baptists, Disciples — and established ones — Episcopalians, Presbyterians, and Unitarians (Blumin 1989). Foreigners were amazed at the level of piety in America, and accounts abound with descriptions of religious fervor (Ratzel [1876] 1988; Tocqueville [1836] 1945; Trollope 1832; also see Morgan 1973). Over the course of the century, more powerful means of social distance and moral evaluation were made in terms of a combination of ethnicity and religion, so that sectarian and established churches contended against the Catholic church and other immigrant churches over the proprietorship of existing social and cultural arrangements (Blau, Redding & Land 1993).

It would appear that the provisions of the First Amendment would dilute the role of religion in secular matters. Wills (1990) argues that, paradoxically, the separation of church and state enabled an intense religiosity (also see Demerath & Williams 1992). Thomas Jefferson, a Deist who had penned the First Amendment, contended that a "wall of separation" between church and state would actually enhance opportunities for religious mobilization: "free argument, raillery and even ridicule will preserve the purity of religion" (1950:549). Similarly, Madison justified separation in that an established state church would "retard Christian evangelizing" (1910:306).

Varieties of Morality

Differences in doctrine between the established churches and the sectarians were reflected in different conceptions of morality and reform. Established churches had somewhat formal church practices and shared a theology that stressed the uncertainty of salvation. Established denominations more readily

viewed church matters as coordinate with state interests and increasingly withdrew from direct involvement in social reform and charity efforts, relying instead on centrist approaches to reform, such as civic projects and legislation. In contrast, the sectarians had relatively communal and decentralized church bodies and embraced beliefs in salvation. Sectarians conceived of grace as attainable and, placing great emphasis on the community of believers, viewed reform efforts to be a matter of helping individuals in seeking redemption (Hutchison 1989; Lipset & Raab 1978; Niebuhr 1929; Troeltsch 1931).

Moral reform throughout the nineteenth century largely reflected these divisions between the established churches and sectarians. Early sectarian social reform movements in the 1830s defined issues in individualistic terms, and amelioration, not regulation, was the approach to social problems such as liquor and prostitution (Boyer 1978). In contrast, the American Moral Reform Association, and later the National Reform Association, were largely supported by established churches and emphasized "regulationist" or legalistic strategies, working through local and state legislative bodies and police departments (Baltzell 1964; Handy 1991; Pivar 1973).

Increasingly, the regulationist reform agenda of the established churches came to prevail over the more individualistic reform strategies of evangelicals, leading to the adoption of antivice legislation in the mid-1870s (Beisel 1993). Antivice campaigns had been waged throughout the nineteenth century, but never before had these campaigns been so infused by interventionist logic and legalistic strategies (King 1989; Timberlake 1963; Tyack & Hansot 1982). It was in this particular historical context that Matthew Arnold "an ardent establishmentarian and advocate of interventionism" arrived in the U.S. with considerable fanfare. Before describing the significance of his emblematic visits, it is necessary to indicate that urban Americans had earlier accepted fine arts traditions but repudiated them in the early decades of the nineteenth century.

Nineteenth-Century Arts

In contrast with the U.S., the visual arts flourished in Europe throughout the nineteenth century (Holt 1979, 1981). After 1793 a salon was held almost annually in Paris that was open to artists of all nationalities; there were regular public exhibits in England, Berlin, and Rome during the first half of the century; and after 1850 there were major art exhibits in many other cities as well, including Florence, Munich, Naples, and Brussels. In virtually every European country, art was fully institutionalized, supported by the state and accompanied by a dense network of artists' associations, critics, publications, private galleries, and buyers. Art was not, as is sometimes claimed, only for private collectors. The Louvre was opened in 1793 as a public museum and throughout the nineteenth century exhibits and competitions were public events, and art galleries in the largest cities, according to Holt's (1979, 1981) accounts, did a brisk business in sales. Although it is the case that art exhibits and sales were predominantly in the private sector and most public museums were founded after around 1850 (Blau 1995), the visual arts were as much taken for granted among the urban bourgeoisie as music, literature, and drama.

Americans, quite in contrast, were indifferent to the visual arts, if not overtly hostile, as their attitudes were described at the time by artists (Dunlap 1834; Green 1966; Jarves [1864] 1960). A telling indicator of this is the large number of American artists who spent most, or all, of their time abroad. This includes virtually all the currently acclaimed nineteenth-century American artists: John Copley, John Trumbull, John Vanderlyn, Washington Allston, Samuel Morse, Thomas Cole, Henry Inman, George Bingham, Winslow Homer, William Page, George Inness, William Chase, William Morris Hunt, Thomas Eakins, Francis Millet, Mary Cassatt, James Whistler, and John Singer Sargent.

This antagonism to secular painting did not, in fact, dominate in colonial and early postcolonial America. Painting was a reputable career and possessing works of art was not uncommon in New England through the end of the eighteenth and in the early decades of the nineteenth century, and there was a significant effort made by a small minority of artists and patrons to fortify American artistic traditions in art associations in major northeastern cities (Harris 1966). However, public opinion was becoming increasingly suspicious of aesthetic and literary tastes unchecked by plain standards of religious self-denial (Cmiel 1990; Kasson 1990). Around 1800 John Adams failed in his efforts to persuade Congress to pass laws promoting the arts and literature (Cummings 1991) and an 1815 congressional declaration stated that fashionable dress, intellectuality, leisure, and art were "foppish instruments of the devil" (Bruchey 1965:198).

The origin of this surge of what Bruchey (1965) terms "puritanicalness," at the beginning of the nineteenth century, was, according to many American historians (May 1976, 1983, 1991; Miller 1965; Nye 1960; Perry 1989; Shi 1985), the manifestation of the Second Awakening from around 1795 to 1835. "Puritanicalness" thoroughly rent the social fabric. It was responsible for a precipitous decline in intellectual life in the first decades of the nineteenth century (May 1976), and accompanied a dramatic and sudden adoption of vernacular and informal American English (Cmiel 1990). The rejection of English and Continental models, notably establishment religion as well as intellectual and artistic traditions, was consistent with the evangelical tenet that religion was a "matter of the heart" (Shi 1985; Walters 1978).

Artworks after the 1820s were increasingly scrutinized within this new moral framework. Evaluative criteria shifted to spirituality and religious sentiment, and the "painterly" traditions that continued to dominate in English and Continental art were rejected. Italian and French art was suspect for such obvious reasons as its nudity and traditional patronage by the Catholic church and the aristocracy, but even English landscape paintings and portraits, which in postcolonial America had been highly regarded, were viewed with suspicion by the American public and collectors. Those U.S. artists who continued to paint in the secular tradition of their English contemporaries — such as Constable, Millais, Hunt, and Turner — were virtually ignored by American collectors (Harris 1966), and, as already noted, there was a sustained migration of artists to England, France, and Italy.

Artists themselves were frustrated by the displacement of aesthetic values by religious ones. Dunlap (1834) complained that in the many cities he toured with his paintings, local clergy would be called upon to evaluate and judge his

works for their religious worth. By the middle of the century, artists began to accept these conditions and along with writers justified their work under the broad umbrella of transcendentalism (Shi 1985). In an article in the *Crayon,* Durand (1855:97) admonishes, "it is only through the religious integrity of motive by which all real Artists have ever been actuated."

Art historian Joshua Taylor (1976) describes the widespread influence of the Society for the Advancement of Truth in Art, whose publication the *Path* "often reads like a religious tract" (123). Neil Harris (1966) summarizes the dilemma of the nineteenth-century American artist by quoting from a Yale scholar of the era who described the painter's situation as having to work with a "moral alphabet with divine symbols" (303).

After the Civil War, the largest northeastern cities nourished small communities of artists and art associations, but artists largely worked under the precept that art must serve the purposes of moral instruction and be an instrument of virtuous education. Transcendentalists packaged their efforts as a grand syllogism: divinity is to morality as morality is to nature, and as each is to art (Harris 1966). There was no conception of an independent artist or of an art that was autonomous from religion (see Pelles 1963). Green (1966) summarizes in his comprehensive survey of American art that the slow development of American art (relative to the pace of change in Europe) was due to the encumbrance of standards of morality imposed on painters. Without a sustained philosophical tradition that ennobled art within the terms of the Enlightenment tradition, American art was brought under the umbrella of popular religion that emphasized that Christian morality offered the overreaching justification for enterprise, reform, education, and household. Art and literature would serve to justify this grand unity (e.g., Bruchey 1965; Taylor 1976).

To account for developments in the 1880s and 1890s, leading to a full-fledged autonomous art movement in America prior to World War I, requires not only recognition of elite support, but also a framework by which we can interpret changes in the way in which art was defined. This involves two translocations in the institution of art versus nonart: first, a redefinition of art so that it was outside the orbit of religious evaluation, and, second, the clarification that art was hermetic and resided only within a realm of aesthetic — that is to say, interpretive, individualistic, and noncollectivist — values.

Fin-de-Siècle

Art acquired legitimacy at the end of the nineteenth century because of elite sponsorship and the decoupling of aesthetic from religious values, but transformations within art traditions accompanied these changes. Illusionist paintings by Homer Martin, George Inness, and William Harnett became popular in the 1880s, and works by Albert Pinkham Ryder in the 1890s were abstract and sensuous. These developments represented a clear betrayal of the aesthetic canon. One account of this transformation is that the advent of photography pushed artists toward abstraction (Orvell 1989). Other accounts describe the role of international travel, the arrival of immigrant artists in the U.S., and the

growing size of New York's bohemian community. All these may be important, but it can be argued that the transformation had to be endogenous to the institution of art (Schapiro 1978).

By the 1920s the earlier stark contrasts between American art and European art were becoming blurred, and by the 1940s the U.S. emerged as the leading contender in modernism and abstract expressionism. The puzzle is, what intervened between the 1880s and the 1920s that resolved the contradiction between religious and aesthetic values or allowed for the increasing autonomy of art? The explanation lies at the profound level of institutions, but if we are to understand the toggling mechanism, it is useful to consider the shift in public perceptions that accompanied the Arnoldian movement. People's beliefs and values refer to, and are defined by, specific events and charismatic individuals (Weber 1946).

THE UNCOUPLING OF ART AND RELIGION

Matthew Arnold's visits to the U.S. in 1883 and 1886 facilitated the rupture between religion and art, or at the very least defined the emblematic moment of the cleft in the heretofore unified and legitimate institution of culture that embraced sectarian conceptions of morality and art.

Levine (1988) contends that it was Matthew Arnold who "was perhaps the single most important disseminator of such [indifferent] attitudes [about high culture] and [who had] an enormous influence in the United States" (223). At first this appears implausible. Arnold taught poetry at Oxford and was thoroughly High Church, a critic of evangelism, appreciably undemocratic, a proponent of strong state rule, and quite contemptuous of the unkempt and dirty populace (Wilson 1960), Arnold seems an unlikely candidate for weakening the hold that popular religion had on the arts in America; his elitism and antisectarianism would appear to render his polemics unsuited to the climate of opinion in America.

Understanding why Arnold was generally popular and influential is not so straightforward. It cannot be based, as Levine (1988) claims, simply on Arnold's defense of high culture. Americans had already rejected high culture on religious grounds.

Arnold's visits were not merely the occasion for a few wealthy philanthropists to learn more about European art or for intellectuals to justify themselves with an indifferent public. These visits were widely publicized around the nation and his talks received considerable coverage in popular dailies and magazines (Pratt 1988; Raleigh 1957; Wall 1970). Religious tensions were pronounced during these decades, and American intellectuals were wary about overloading secular thought with too many encumbrances, and no American philosopher had ventured to test the line between secular aesthetics and religious morality (Commager 1950). However, Arnold was advantaged in this respect; his allusions to religion in England concealed his considerable distaste for sectarianism from his American audiences.

Arnold was persuasive because his appeal, that "the best that has been thought in the world" is achieved through "the study and pursuit of perfection," signaled to Americans that to be "best" and to pursue "perfection" meant

education and the pursuit of knowledge and was not interpreted as being in conflict with homegrown religion (1897:xx; see Eliot 1932; Livingston 1986; Spender 1963; Trilling 1977; see also Bell 1976). He provided a language to talk about secularism and learning, and an entire industry of criticism flourished in the subsequent decades.

Arnold's accomplishment was to provide a cultural justification for removing art from the dictates of religious morality to those of secular morality. His general popularity and wide influence may be traced to several conditions. First, the American academy was not very theoretical, and neither was Arnold (Abrams 1989). His judgments about the arts were couched in terms of their expressive and redemptive qualities, affirming Weber's observation that art in an intellectualizing period appeals to subjectivity in its competition with religion. Second, Arnold appealed to the pretensions of the upper class and the aspirations of the growing middle class (Lears 1983), while providing an aesthetic framework for urban reform (Bender 1987) and helping academic elites achieve a recognition they had long sought (Cremin 1988; Raleigh 1957).

Third, Arnold spoke the language of "difference" in a milieu that was creating difference. Throughout the 1870s and 1880s there were growing economic inequalities, and accompanying the increase in immigration from central and eastern Europe was a dramatic rise in popular forms of nativism as well as in social Darwinism. The "vogue of Spencer," according to Hofstadter ([1944] 1992), drew on the same language and many of the same principles as the "vogue of Arnold." Specifically, both emphasized that inequalities arising out of competition were inevitable and justified; that ethical hierarchies were more or less coincident with social and economic — if not biological — ones; and both held popular religion and social reform in disdain. It is interesting that one of the most prominent supporters of social Darwinism, Andrew Carnegie, sponsored both of Arnold's visits (Wall 1970) and Herbert Spencer's in 1882 (Hofstadter [1944] 1992).

That Arnold's definition of art had a pretentious note probably helped considerably in the short run: there were growing economic inequalities, a surge of immigrants from eastern and southern Europe, and the urban middle classes were expanding. In subsequent decades, as we shall later see, the art world rejected Arnold's literal interpretations of aesthetic value, and he achieved little lasting fame as an original philosopher (Abrams 1989). Yet the transformations that occurred between 1880 and 1900 make more sense if Arnold is viewed as a pivotal figure than if he is not. It is also useful to show how he advanced different accounts in England and America, because this further helps to illuminate how religion retarded artistic developments in America, although it did not particularly do so in England.

Matthew Arnold in England and America

Culture and Anarchy, which was written in 1869 and revised in 1875 and was subsequently coupled with *Friendship's Garland* in 1899, was intended for an English audience that was steeped in the tradition of the Church of England. Introduced in all editions as an "Exhortation to the Society for Promoting

Christian Knowledge," it is a diatribe against popular sectarianism and a vigorous defense of a higher culture that is both moral and rational. A stark dichotomy is drawn between beauty, intelligence, classical learning, and morality on the one hand, and disestablishment, debasement of authority, superficial learning, and anarchy on the other.

Arnold's (1899) attack on sectarianism is direct: "Because to enable and stir up people to read their Bible and the newspapers, and to get a practical knowledge of their business, does not serve the higher spiritual life of a nation so much as culture, truly conceived, serves." And then he adds, "just what America fails in" (xxvii). Rhetorically, he asks, "how shall we persuade our Nonconformist that his time spent in agitating for the abolition of church-establishments would have been better served in getting worthier ideas of God and the ordering of the world, or his time spent in battling for voluntaryism [sic] in education better spent in learning to value and found a public and national culture?" (201).

Arnold's answer lies in a convoluted argument that places the blame as much on economic liberalism, the idle rich, the lack of state planning, as on the sectarian churches. He defends organized capitalism and contends that the disinterested endeavors of human perfection — which can be traced back to Hellenic times — ought to be protected from the romantic and irrational religious traditions of sectarianism. Arnold (1899) reclaims the arts for classical learning and established religion:

> The great works by which, not only in literature, art, and science generally, but in religion itself, the human spirit has manifested its approaches to totality and to a full, harmonious perfection, and by which it stimulates and helps forward the world's general perfection, come, not from Nonconformists, but from men who either belong to Establishments or have been trained in them. (xvi)

Although Arnold's American lecture tours were widely publicized and well attended (Levine 1988; Wilson 1960), relatively few Americans were actually familiar with his English writings (John 1981; Mott 1938; Raleigh 1957; Shi 1985), and evidently, it was only in the literary salons of Boston and New York that conservative intellectuals actually read and discussed his earlier works (Shi 1985). The lectures given in 1883 and published as *Discourses in America* were based on very different themes from his earlier, English writings. The first discourse, "Numbers," briefly eludes to "excellent Puritan discipline" (Arnold 1885:71), a striking contrast to his description of the Puritans in England as "incomplete and mutilated men" (1899:11). But with this rare exceptional comment about religion, the first "discourse" is largely a discussion about the advantages of America's diversity, while signaling that there may be difficulties with democratic and majoritarian government:

> Perhaps you will say the majority *is*, sometimes good; that its impulses are good generally, and its actuation is good occasionally. Yet, it lacks principle, it lacks persistence; if to-day its good impulses prevail, they succumb tomorrow; sometimes it goes right; but it is very apt to go wrong. (1885:6-7)

Arnold trusted, however, that superior intellectual leaders — the "remnant" — would have the wisdom to lead. The second discourse, "Literature and Science,"

is a defense of the study of literature because it strengthens noble sentiments and profound understanding. In contrast, Arnold (1885) rails against the practical sciences, adding that a "little of mathematics, even, goes a long way" (108).

The final discourse, "Emerson," is a laudatory account of transcendentalism and Emerson, with one mere teasing remark about the sectarians of England: "Carlyle's insistence on labour, righteousness, and veracity pleases [the preachers] of the popular religion; his contempt for happiness pleases them too" (200).

Arnold negotiated the troubled waters in America by emphasizing American exceptionalism (that is, for him, the energy and diversity of the population), praising the homespun tradition of transcendentalism, and appealing to the emerging elite. By stressing the importance of humanistic learning, he gained the support of intellectuals, such as E.L. Godkin, Charles Eliot Norton, William James, and Henry Adams, who themselves had been defensively battling for elite, classical education (see Bender 1987; Shi 1985). His sympathies for strong state control resonated with the regulationists' strategies for moral reform and antivice activity. And, through his friendship with Carnegie, he supported efforts to launch a high arts philanthropic movement that ostensibly transcended religious divisions and that helped to establish bonds between American and European collections and collectors.

Arnold's occasional denunciation of sectarians was aimed not at American Methodists, Disciples, and Baptists, but, duplicitously, at English "dissenters." What Americans learned firsthand from his lectures and also from press coverage consisted of his praise for American industriousness, his high opinion of native literary traditions, and his enthusiasm for the emerging public education system. His defense of high culture was cast in the imagery of social reform, and, most especially, in terms of class (exemplified in the "remnant" and defined in terms of morality and conduct). In was in these establishmentarian and statist terms that he defined culture as "the best that has been known and said in the world" (1897:xx).

The Gordian Knot of Institutions

Increasingly after Arnold's visit, the rhetorical defense of art had less to do with spiritual values and more to do with refined taste, classical canons of beauty, and distinctions of social class. The custodians of high culture that followed the Arnoldian line claimed the moral high ground as composing "the natural aristocracy of virtue and culture" (Shi 1985:157).

The initial steps in the institutional transformation that made possible an autonomous art involved both an elevation of art to a positive good and a connection of refined tastes with status in the social hierarchy. This is the Arnoldian legacy. But this legacy problematized high art because it wedded art to class inequalities and substituted class morality for religious morality. The artist was hardly free. How, then, can we account for the emergence of an American avant-garde in about 1910 (see Shapiro 1976)? One factor was an attack by the Mugwump intellectuals, such as Thorstein Veblen and Edward

Bok, who lashed out both at the American wealthy and at the conservative intellectuals who fit the Arnoldian mold (Shi 1985). To be sure, associations between status and cultural tastes persisted through the twentieth century (Lamont 1992), but these are practical, not ideological, associations, and artists worked after around 1915 as if they did not exist. This claim of autonomy is precisely the rhetorical justification for "art for art's sake" or the avant-garde, much earlier proclaimed in England and the Continent, but never fully accepted or understood in the U.S. in the nineteenth century.

In short, there remained at the end of the 1880s another Gordian knot that had to be loosed before art could acquire an intrinsic freedom that is associated with the avant-garde (Crane 1987), namely, a disavowal of morality, a disregard of class (and patronage), and a denial of tradition. In philosophy and popular thought, social Darwinism was losing its appeal and pragmatism was taking hold. In aesthetic theory the knot was untied by the American philosopher Santayana ([1896] 1955), who in turn was influenced by his contemporary William James, who had repudiated Spencerian evolutionary theory and the doctrines of determinism and inequality. Santayana's accomplishment was to distinguish art, which has no utility, from morals, which involve benefits and have practical significance.

According to Santayana, and consistent with subsequent developments in pragmatism, there are no transcendent criteria that are appropriate for evaluating art and, likewise, no possibility of universal standards or of evolutionary selection, owing to differences among individuals, historical periods, and nations. In fact, art has every right to be "ugly" (Santayana [1896] 1955:29), for its worth lies in its expressive and subjective values. Santayana accomplished two things for the American artists and art. First, he severed art from religious norms, and, second, he situated American art within Kantian aesthetics. Instead of expressing either a manifest historical destiny or the truths of moral and social hierarchies, artworks embodied the artist's creative vision. Lagging behind their European counterparts (Taylor 1976), American artists found by about 1920 a new conception of art, one that was explicitly antibourgeois and anticanonical. In the American context, it was Santayana who provided the secular language for the aesthetic experience. He stated that there is no accounting for art as the "adumbration of divine attributes" (Santayana [1896] 1955:11), and art's only purpose is that it is "*prima facie* and in itself a good" (Santayana 1906:115).

The Armory Show in 1913 was the enacted moment of the birth of modernism in the U.S. Here European avantgardists joined with a small number of American painters. There was a broad representation of early cubism, surrealism, social realism, and early expressionism. And from that moment, art could institute itself as an autonomous dynamistic movement, that is, as a movement that was self-destructive, self-alienating, and progressive (Crane 1987; Hess & Ashbery 1967; Kuh 1965; Shapiro 1978).

The autonomy-of-art position is that "a work of art is the creation of a novel order whose value lies in no end other than its own integrities" (Ross 1982:89). This definition begs the question, autonomy from what? The answers have been autonomy from technology and economy (Benjamin [1936] 1968; Marcuse 1978), from class (Wolff 1983), from politics (Koselleck 1988; Rosenberg 1965), from

theory (Gadamer 1975), and from language (Barthes 1987). From a sociological point of view, art is just a label (Becker 1982). The paradox, of course, is that evaluations become arbitrary in the absence of theory; the impersonal forces of the market of buyers, curators, and critics are difficult to distinguish from their evaluations when the avant-garde rests on the principle of self-destruction. Advanced finance capitalism rests on the conception of arbitrary financial value and an impersonal market. This is not inconsistent with a conception of art that is autonomous, morally agnostic, and independent of any group's claim to a unique identity. Like currency, art became self-referential in its evaluation while universal in its appeal, yet still authorizing subjective escape from capitalist values.

Finally, we can explore the possibility that art is again in the midst of flux, both with respect to the theory-practice problem of meaning (Baxandall 1985; Bürger & Bürger 1992; Danto 1985) and its relation with the economy (Blau 1995; Dubin 1992), but this can be only brief and speculative.

Discussion

Although institutional theory has emphasized the taken-for-granted character and legitimacy of culture, it is argued below that institutional potency depends on antagonisms between institutionalized domains. In the U.S. during most of the nineteenth century, art was so deeply embedded within a religious and moral framework that art could not be justified in its own terms (expressive, as form, texture, decorative). Yet by the end of the century it was possible to forcefully oppose art to nonart as secular aesthetics attained independence from religious morality. Initially, this was achieved within the Arnoldian framework that placed art in the sphere of civilization, positioned at the top of a social and cultural hierarchy.

Santayana provided the philosophical justification for the avant-garde, and he firmly laid down the principles that would free art from every institutional linkage external to the world of art. This extraordinary development pitted art against nonart as a constantly changing but historically self-conscious institutional complex. Nonart included works outside this complex, such as kitsch, popular culture, representational art, and folk art. Art could be abstract "expressionism, photorealism, symbolism, cubism, or whatever," as long as it was poised as if intent on the destruction of what went before. That is, art derived its potency in terms of an aesthetic canon that provided a language for distinguishing art from the commonplace and a vocabulary for describing stylistic transformations (Danto 1981). In an ironic way, art as ideology was independent of economy, politics, and religion, whereas the reception of art depended on its legitimation as a cultural institution within the class structure. The connoisseurship that grew out of the Arnoldian framework can hardly be distinguished from the secular habits of the urban middle and upper middle classes.

What has been recently widely viewed as the death of the avant-garde by cultural theorists (Crimp 1983; Danto 1985; Dziemidok 1985; Jameson 1991; Ventós 1980) has been interpreted by social scientists (Blau 1995; Crane 1992;

Dubin 1992) as the collapse of the distinction between popular and high art. Within the circles of art criticism and theory, art versus nonart now draws on different distinctions: subversive versus nonsubversive (Aronowitz 1994), social praxis versus triviality (Bürger & Bürger 1992), and engagement versus autonomy (Abrams 1989; Bernstein 1992). And in the political arena, art has become the ground of contention and debate both about individual identity — race, gender, and sexuality — and about group rights — those of women, blacks and other minorities, noncitizens, and the politically disenfranchised — and also about the rights and obligations of memorialization.

If high culture has disavowed its own lineage by repudiating its historical roots in the tradition of the "high cultural humanism" of Arnold and Comte (Said 1978:228), can we conclude that it has incorporated popular culture? This line is hard to draw for certain reasons. Both popular and high culture celebrate an autonomy of self and subjectivity, the admixture of codes of the past and the present, and the presentation of the wicked and the playful over the banal and the sublime. It is possible to assert that there are essential differences, assuming that we define high culture as that which is not dependent on commercial support and that we distinguish popular culture that is rooted in the practices of local groups from commercially supported culture.

Commercial elites — the makers of much that passes for popular culture — have *practical reasons* to advance the expressive cultures and traditions of local groups, including the oppressed, whereas the proponents of high culture assert *moral reasons* to advance the expressive cultures and traditions of local groups, especially the oppressed. Commercial elites cannot greatly violate habits of the heart and lodge irony and subversiveness within such habits. Contemporary high culture elites have no such logic, and must — for the sake of consistency — raise questions about their own legitimacy as they raise questions generally about power, oppression, subordination, and group practices. For these reasons, we must view the relations between commercial culture, the high culture tradition of the avant-garde, and versions of local group culture as being more potentially contentious than is commonly recognized in the social sciences, and, indeed, anticipated by Weber, who emphasized the disengagement of modern art.

If Weber failed to anticipate the current reengagement of art with politics and ethics, he provided a sketch of a general framework that can be elaborated to account for major transitions that occur when worldviews are fundamentally contradictory and there are competing vested interests. Yet this suggests a modification of institutional theory, namely, that various potentially contradictory institutional models may exist simultaneously and compete for legitimacy. In large societies, toggled shifts often appear inchoate. Thus, the toggling of institutional change is likely to involve transformations that cannot be predicted with a high degree of precision, yet because competing discourses and cultural practices are contingent on interests, as Weber emphasized, ascendant institutions are amenable to manipulation.

Announcement

Call for Papers

Current World Leaders
International Issues

Current World Leaders, published for 39 years, is accepting papers for publication in 1997.

Each of three international issues will focus on a specific topic::

April: Media and Politics
August: Nationalism and Ethnic Politics
December: Women and Politics

We intend to cover at least tow, and preferably several, perspectives on each topic. For example, the issue on Women and Politics might have one article discussing the changes wrought by women gaining equality and increasing their power within the U.S. Or, it might contain an article presenting a cross-national analysis of the effects on various cultures and political systems of increasing equality for women. We are calling for previously and unpublished papers that present a particular point of view on the topics described above. Articles should be between 4,500 and 10,000 words long.

We also welcome suggestions for other topics.

For more information including deadlines and a style guide, contact:

Thomas S. Garrison
Editorial Director

From Protest to Change of Regime: The 4-19 Revolt and The Fall of the Rhee Regime in South Korea*

QUEE-YOUNG KIM, *University of Wyoming*

Abstract

Under what conditions do protest movements develop into revolutionary upheavals and force a change of regime? This article examines the impact of economic deprivation, power difference, public opinion, and critical resources on participation in the waves of a protest movement before and after violent coercion. The empirical setting for our analysis is the historical 4-19 Revolt and the fall of Syngman Rhee s regime in South Korea in 1960. The results indicate that economic deprivation was the most important cause of the collective protest during the first phase of the movement. The authorities' violent response to the protest and the mobilization of public opinion against that violence facilitated protest and transformed it into a major upheaval that overthrew the regime.

Why and how does protest occur, develop into a revolutionary upheaval, and overthrow a regime? The dynamic process of conflict, in which protest becomes revolutionary, involves a sequence of patterned encounters between growing social forces and the power of the state. As Coleman (1990) observes,

> Revolts do not involve a simple two-party structure, with the authorities as one party and the population, considered as a homogeneous mass, as the other. The opponents of the authorities are ordinarily a very small subgroup of the population at the beginning of a revolt, and most of the populace is not active on either side. But even those who are initially uninvolved differ in various ways relevant to the conflict. They cannot be characterized according to a single dimension alone (such as their relation to the means of production, which is how Marxist theory characterizes them). Any population is differentiated in many ways: region, ethnicity, age, class, economic status, and so forth. What is relevant from the view of a theory of revolution is the relation of members of the population to authoritative actions. (490-91)

* *I appreciate the valuable technical comments and constructive suggestions on earlier versions of this article made by Audie Blevins, Burke Grandjean, and David Ashley. This research was supported in part by NSF Grant SES-9115830. Direct correspondence to Quee-Young Kim, Rm. 410, Ross Hall, Department of Sociology, University of Wyoming, Laramie, WY 82071-3293.*

 Social Forces, June 1996, 74(4):1179-1209

Any adequate theory of revolutionary dynamics must consider the relationship between the conflictual encounters and the factors that promote the growth of social forces, to explain how a "small subgroup of the population" gains substantial support for its cause for protest and why the regime suddenly loses the power to control the challenges from below. Tilly (1978, 1993) defines such a situation of extensive political conflict as revolutionary. Specifically, a revolutionary situation combines "(1) the emergence of rival claims to the state; (2) the commitment to those claims by a significant segment of the citizenry; and (3) the incapacity or unwillingness of rulers to suppress the alternative coalition and/or commitment to its claims" (Tilly 1993:10-11).

Protest at first does not usually make an exclusive claim to the state, and thus rarely develops into a revolutionary situation. In the beginning it may appear as legitimate opposition to the authority by a small group of people. Protest becomes illegitimate and thus revolutionary when the authority interprets the demands as a threat and a challenge to its monopoly of power. The conflict between protesters and authorities becomes revolutionary when sovereignty — the state's absolute monopoly on coercive force and the right to exercise that force — is increasingly challenged and rendered ineffective (Tilly 1978). Meanwhile the choices available to challengers and authority "become more and more limited, excluding the options of conciliation and negotiation, while the political conflict becomes more and more unlimited" (Stinchcombe 1965:171). To paraphrase Tilly (1979), the choice of repertoires of repression and contention becomes more and more limited. The rules and procedures of encounter change radically; conflict increases between some members of the population and a changing set of authorities in the nation-state.

Waves of protest can grow rapidly; they may become revolutionary in response to violent coercion as defiance against authority develops into massive demand for institutional change. Claims can escalate into more basic demands, and the basis of support also can expand through waves of protest. Such forces of political upheaval can produce a transfer of power, including a change of leadership and regime.

A revolutionary situation can produce a variety of revolutionary outcomes. "A great revolution entails by definition both a basic split in the polity (a deep revolutionary situation) and a large transfer of power (a serious revolutionary outcome). A revolt may involve an extensive revolutionary situation, but limited transfer of power" (Tilly 1993:15). Some transfers of power occur so gradually, and the actual tenure of power is so brief, that they may not be noticed as a revolutionary outcome. Some transfers of power may occur at the level of regime, not at the level of the state. The major distinction between revolt and revolution is whether the transfer of power occurs in the regime or in the state.[1]

A regime is a formal government with distinctive rules and decision-making procedures; at the same time it is an informal organization in which the center of political power possesses principles and norms (Krasner 1983). "A regime," says Lawson (1993), "determines how and under what conditions the power of the state is exercised" (187). In addition, a regime is a power structure of the state. The state, in turn, is the structure of domination and coordination with the right to monopolize and to exercise coercive force. Unlike a major revolu-

tion, a revolt involves limited transfer of power but it may change the power structure of the state by overthrowing a regime.

A regime becomes weak when the relationship between norms, principles, and rules appears to be increasingly incoherent and contradictory, or when actual practice becomes increasingly inconsistent with the principles and norms. It becomes weaker and may even fall if the challenge to the ruling elites is supported by not only a substantial segment of the citizens but also by some of the ruling elites, and if the authority becomes unable or unwilling to suppress this challenge. Regime change is a change in the principles and norms that govern the rules and procedures.

Authoritarian regimes are more vulnerable than democratic states to protesters demands because charges of contradicting principles may escalate into the issue of leadership and extensive power at the center. The principles and norms of constitutional democracy limit specifically how power is to be exercised. As Lawson (1993) remarks, "by prescribing such limits and establishing the rules of political conduct, constitutionalism underscores the norms of democratic politics and gives rise to a much clearer distinction among state, regime and government. In authoritarian states, however, power is basically undivided and monopolized by the few at the top. No distinctions exist among state, regime and government. The ruling party often identifies itself with the state" (187). Therefore, in such states, the government cannot be changed without changing the regime. A regime change thus resembles a revolution because it implies changes in the dominant power structure of the state.

How then does a revolutionary situation emerge? Specifically, what conditions transform protest into a rebellion? What are the causes and consequences of violent political conflict? Why and how does the protest movement expand so much that the rulers cannot or will not suppress it? The purpose of this article is to identify the conditions that change protest into revolutionary upheaval under the influence of violent coercion.

Despite the extensive literature on protest and rebellion, few studies offer explanations for the transition from protest to rebellion. Even fewer studies explain a national change of regime from a time-series perspective while considering the variation in the local circumstances of collective action. Employing mostly social data and historical information, I combine cross-sectional data on cities with time-series data on collective action to explain the origins of protest and the causes and consequences of violent coercion. The empirical backdrop is a historical revolt in which students and citizens of major cities "rose up" and overthrew Syngman Rhee s regime in South Korea in 1960.

Available theoretical and empirical studies on protest and revolutionary movements mostly come from experiences in Western societies that are different in culture, historical condition and institutional context from those that existed in South Korea in 1960. Although the event that we study belongs to the general category of protest and revolutionary movements, the way in which such processes unfold may vary from culture to culture and the pattern of processes that one finds in one place may not conform to the theoretical models that had been constructed on experiences from another place and time. Often, these theoretical models taken as a whole are not coherent and therefore do not offer any coherent explanations to the pattern of ontologically similar processes.

However, some of the main ideas contained in these models offer powerful insights to organize and illuminate in a theoretical way the story of how people rise up and overthrow their government. Our purpose here is not to apply any dominant theoretical model to the case but to use the main ideas from different theoretical sources to explain the pattern of sequences that involved interactions between forces of opposition and the authority under different local settings. We also identify the causal factors that account for the origin of protest and transition from protest to change of regime. First, I will briefly review the major arguments that purportedly explain the rise of protest movements. I will discuss the conditions of violent political conflict and will relate the effects of violent coercion to the subsequent expansion of protest. Next, I will present a brief historical narrative of the event. Then, combining theoretical insights with the narrative, I will discuss the research design and analytical procedures.

Origins of Protest

One of the most controversial explanations of the rise of the protest movement is economic deprivation. This thesis states that no major protest movement will occur unless a substantial degree of deprivation exists in the population. Deprivation theory emphasizes substantive grievances as a motivation for protest, and predicts that protest will occur because of discontent resulting from economic conditions that impinge on individuals' sense of well-being.[2] According to this theory, unemployment, inequality, poverty, and unsatisfactory living standards are the primary causes of rebellion (Gupta 1977; Gurr 1970; Muller 1972, 1979, 1986; Muller, Dietz & Finkel 1991; Walton 1984; Walton & Ragin 1990). Some deprivation becomes intolerable and fosters revolt, especially when improvements in socioeconomic conditions are followed by apparent deterioration (Davies 1962) or when conditions do not agree with one s expectations in relation to one s capability (Gurr 1970).[3]

Another, equally compelling thesis, based largely on resource mobilization theory, suggests that deprivation does not produce collective action. Poor, displaced, and disenfranchised groups will be "underrepresented in the census of popular activism," according to Aya (1984), because "people with ostensibly the meanest grievances to fight often have the meagerest resources to fight with" (330). Hence the individuals who initiate protest usually are those who are "better situated" (Eckstein 1989:37), a "resourceful part of the critical mass" (Oliver, Marwell & Teixeira 1985) "whose economic basis, social standing, organizational network and political connections afford them the capability to press their claims in the political arena" (Aya 1984:330-31). Mobilization for protest occurs, according to this view, not as a result of the aggregation of individual discontents but because of the ability to use resources that provide the basis for solidarity in organized groups (Aya 1984; Jenkins 1983; Oberschall 1978; Snyder & Tilly 1972; Tilly 1978).

Mobilization for action usually occurs where one finds a large number of ready-made organizations, circles of friends, and especially an organized community of critical consciousness, such as universities and colleges. These places accentuate the existence of such a community, as well as a core of

activists who have more resources than the general population and are more strongly committed to the general principles of justice. Thus students and professionals usually lead the protest because they are "a critical mass of highly interested and resourceful actors" (Oliver & Marwell 1988:1) and command critical resources.

In addition to critical resources, political opportunity structure appears to be crucial in explaining the rise of a protest movement. No protest will occur when the balance of power between the opposition and the regime overwhelmingly favors the few rulers at the top. Protest is common, however, in democratic societies where power tends to be shared through participation in decision-making processes, such as elections. In authoritarian states, power is shared by the people and the government in principle, but in practice it is monopolized by the few at the top. To establish legitimacy, authoritarian rulers conduct elections and seek popular support. The political situation most conducive to collective action occurs when opposition groups are gaining power resources in relation to the ruling coalitions, who meanwhile are losing popular electoral support. The central feature of this, "balance of power" theory is the notion that the differences in power resources over time increase the prospects for both change and for collective action. Decreases in the difference in power resources will increase the probability of protest and political conflict (Kitschelt 1986).

Protest also will occur when protesters expect that public opinion will support their cause. In fact, the mass media in general fertilize the social ground for protest by informing the public about the issues, communicating with potential participants, criticizing the challengers' actions and the policies of authority, and evaluating and dispensing judgment on the political situation. The free press in particular thrives on controversy, exposés, and what Molotch (1979) calls "newsworthiness"; often it criticizes the disjunction between what the authorities ought to do and what they do. The more favorable the existing public opinion appears to be toward the opposition forces, and the more critical of the prevailing authority, the more likely it is that protest will occur.

All these factors — economic deprivation, critical resources, differences in power, and public opinion — can influence not only the origins of protest but also the context of political conflict and the subsequent expansion of protest. Some people may participate first and others later, depending on the political opportunity structures, "which facilitate the development of protest movements in some instances and constrain them in others" (Kitschelt 1986:58).

Causes and Effects of Violent Coercion

When the survival of an authoritarian regime is at stake in the face of the strong possibility of a change in regime, conflict between opposition and authority is likely to escalate into high-stakes revolutionary violence. In electoral years, for example, when a transfer of power is in the offing and there is widespread "dissatisfaction with the current authority system and the newly acquired belief that there is some possibility of change" (Coleman 1990: 484), both the elites and the challengers are likely to resort to violence — the former to maintain the power structure and the latter to change it. People who are most aware of the

contradictions between principle and practice will protest that the rules and procedures for making decisions should conform to principles of democracy. When the authority resorts to violent repression of such demands, the latent structural contradictions become manifest. The protesters learn that one cannot change the rules and procedures of the regime without changing the principles and norms, and the regime itself.

Protest can increase the legitimacy of the protesters cause if their numbers are large. Protesters therefore appeal to the public for support and try to mobilize demonstrations as large as possible. Protest, however, involves a peculiar logic that makes it violent when it is large in scale. Large demonstrations indicate the extent of popular support, and usually are disorganized. The demonstrators are emboldened to express their feelings freely in disruptive and creative ways; they are as much protected as encouraged by the size of the crowd. As DeNardo (1985) observed, "there is safety, as well as power, in numbers" (36). Demonstrations become more and more disruptive as they grow larger. At the same time, the regime becomes less able to control crowds as they grow larger, and the implicit threat of continued disruption provokes violent coercion.

Violent coercion increases the dissidents anger and intensifies their opposition when the regime uses it to impose enduring deprivations on a dissident group (Gurr 1980). Summarizing the main arguments of a comparative study of contemporary revolutionary movements, Gurr and Goldstone (1991) state: "One of the most striking features of our cases [of revolution] is the frequency with which the old regimes followed policies that intensified grievances and focused popular anger on the state. In virtually every instance, threatened governments used force and violence in ways that increased popular resentment and active support for revolutionary movements" (334).

Rather than deterring further protest, violent coercion exacerbates the conflict when the opposition forces are economically deprived and when public opinion toward the regime is generally negative. The economically deprived have nothing to lose because they have little stake in the status quo; they will repay violence many times over if encouraged by public support. Once they mobilize, it becomes easier to do so a second time, and the perceived risks decline rapidly in relation to the increase in moral support from the public. Thus one should expect a transition from protest to a revolutionary upheaval when protest is associated largely with economic deprivation and popular public support, and when the protest encounters violent coercion.

If discontent is widespread and popular support for the regime is weak, and yet the repression is violent, the protest will gain more material support and sympathy from "people who have not suffered directly from the government's excesses" (DeNardo 1985:154). That is, the greater the moral outrage toward violence by the state, the greater the participation by various sectors of society is likely to become. "The more diversified the base of resistance," Eckstein (1989) observed, "the more difficult it is for a state to address the varied grievances of groups concomitantly through force or reform" (49). New participants bring new issues and demands into the protest movement. The movements become a major rebellion not so much because the members are united in a cause as because they are united in opposition to authority. The

original goal of protest develops into more extensive demands, creating an urge to replace not only the policies of the government but also the government itself.

We should expect a direct causal relationship between violent coercion and revolutionary upheaval, especially in authoritarian states. In such states, inherent contradictions exist between the principle of democratic constitutionalism, from which the regime draws its legitimacy, and the decision-making procedures that restrict participation by the opposition. The rules governing the relationship between government and opposition are one-sided in favor of the authoritarian rulers. Some oppositions are tolerated, but they lack the constitutional status of a legitimate alternative government, which the people (in principle) have the power to choose. The resort to force by the authoritarian regime brings to life the contradiction between the rules and procedures of authoritarianism and the principles and norms of popular constitutionalism. At the same time, the use of force by the few at the top implies that the state is unable to meet the challenge within the normal legal-rational framework. Such weakness on the part of the state inspires further insurrection, especially when discontent is widespread and popular support for the regime is weak.

The use of force tends to shift the center of power within the regime from one faction to another, to undermine the regime ultimately from within, and to change the fundamental rules and procedures of the regime. Prime ministers come and go; cabinet ministers are reshuffled; the standard bureaucratic procedures are suspended to meet emergency situations; special legal provisions often are invoked. Debates about proper approaches to conflict divide the decision-making group. In Pareto s ([1901] 1991) words, "The declining elite becomes softer, milder, and more humane and less apt to defend its own power" (59). Humanitarian sentiments then become a platform for rallying the opposition. The tough-minded blame the tender-hearted for hesitating to use force, and force is used. Then the "mild" faction overrides the "tough" faction and blames it for having allowed the revolt to go out of control. Then civilian authority may be transferred to military commanders, who may not want to support the regime and the leaders who have violated the people s trust.

The use of force against popular protest undermines the unity and strength of the regime and sharply reduces the range of options. Either the regime must rule continuously by force, if it can to do, or it will fall. The regime is likely to fall when any further use of force becomes unfeasible and the state no longer can command "the right to exercise control" as a "legitimate authoritative action" (Coleman 1990: 470). In this situation, the authorities cannot or will not use force, and the protest movement succeeds in overthrowing the regime.

The 4-19 (Sa-Il-Gu) Revolt

Power struggles between Rhee and his opponents intensified after the Korean War (1950-53) because Rhee and his party (*Chayudang*) apparently were determined to stay in power at all costs. In 1954 Rhee amended the constitution, over strong opposition in the National Assembly, to allow himself to run for the presidency after his second term, which was expiring. Power struggles between

Rhee and his opponents took a radical turn in the 1956 and 1958 elections, however. In 1956 Rhee won only 56% of the popular vote, compared with the 72% he had received in 1952. The opposition (*Minjudang*) lost the presidential race but won the vice-presidency with 46% of the vote, over Chayudang's 44%.

Two years later, the political scene shifted more dramatically in favor of the opposition. In the 1958 National Assembly election, the ruling party lost five of its seats, falling from a dominating 134 to 129 of a total of 233. The main opposition party increased its representation from 47 to 79 seats, one-third of the total. This number was sufficient to block any major attempts by the ruling party to keep the incumbent president in power through constitutional amendment.

The electoral pattern revealed a sharp geographical division between rural and urban districts. In the 1958 election, for instance, the candidates of the ruling party received 39% of the total vote, predominantly in rural areas; candidates in the main opposition party gained 30% of the total vote, mostly in cities. The opposition established its popular bases in cities and drew its resources from that source in its intensified power struggle against the ruling party. The ruling party, on the other hand, mobilized the government's resources to intimidate the voters into submissive loyalty to the incumbent administration. The power struggle paralyzed parliamentary politics and escalated into the electoral arena, involving the mass media, intellectuals, and students (Q. Kim 1983; Pak 1980).

The Rhee regime stood precariously on a contradictory basis of democratic principles that honored freedom of the press and the electoral system as the basis of legitimacy, on one hand, and repressive authoritarian practices on the other. Most of the press was free to criticize and report irregularities in politics; occasionally, however, the government imposed censorship and even closed newspapers, only to ignite greater dissent and more criticism against the regime.

The number of universities in Korea increased from 28 in 1945 to 85 in 1960. During the same period, the number of college students grew from 7,800 to 142,000. College attendance by youths rose from 4% in 1953 to 12% in 1960, one of the highest in the world (Central Education Research Institute 1967; J. Kim 1985:175-80). Students were recruited on the basis of academic merit from a cross-section of regional and class backgrounds. Education stressed general knowledge rather than narrow skills. Formal socialization emphasized national service as the goal of education, and national issues became the dominant topic of conversation among students. The larger the university population grew, the stronger became the students' concern and interest regarding national politics.

The students' opposition to the existing political arrangements was based primarily on the issue of how democracy should be implemented rather than on the desire to institute an alternative system of government. The students rejected their societies' institutions as backward and feudal in comparison with those of Western countries, and they looked to the Western democracies as successful models of economic development. Their support for democracy was correlated with their own educational experience, which emphasized achievement, competitive standards of merit, and equality of opportunity. These traits frequently conflicted with the traditional, particularistic values of the controlling

elite. The students found, however, that political practices contradicted the highly orthodox principles they had learned at school. They criticized the political authorities for not living up to the ideals of democracy and for not carrying out both the letter and the spirit of the constitution. They perceived the political elites as grossly unprincipled and thus immoral.

The event that galvanized the public and drove students into the streets in the spring of 1960 was a blatant rigging of the election, accompanied by political harassment, widespread and crude repression, and sheer political terrorism. The terrorism was justified largely under the pretext of anticommunism; it was argued that President Rhee must be reelected in order to continue the struggle against Communist North Korea. It was possible for the government and the ruling party to manipulate repression because the state controlled the major institutional resources in the electoral process. Thus they could use these resources to their own advantage as they saw fit.

The rigging was a draconian measure, a high-stakes gamble to defy recent voting trends and public opinion. Major newspapers exposed in detail the scheme to steal the election (copied and compiled from several confidential instructions from the Office of the Minister of the Interior to the local police and election management officers) and campaigned vigorously against it, thus keeping the issue alive. Opposition politicians resorted to various measures such as filibusters and boycotting parliamentary sessions to block the ruling party from winning the election by fraud. Repression and political terror prevailed, however, allowing the election to be rigged.

Opposition party workers were arrested without charges, denied access to selected areas, pushed out of observation posts in voting stations, and lynched by "patriotic" gangs. Police mobilized voters in groups of three to five to vote together in a booth, where everyone was instructed to reveal his or her choices to the others. Prefabricated votes were stuffed into ballot boxes before the boxes were delivered to the voting stations. Some boxes from selected districts were deliberately lost in transit.[4]

To the majority of conscientious students, rigging an election was an outright violation of the rules of fair play. When the authorities themselves violated the very principles that the students had been taught in school, the result was a condition of disjunctive justice (Q. Kim 1991; Moore 1978; Stinchcombe 1965:175), which provided the moral justification for a revolt. When asked to explain the motivation for the "dangerous" action, one student replied, "We were so mad, angry and frustrated by the election rigging and police brutality [that] we wanted to demonstrate to the people and to the government that we were not a living corpse" (S. Kim 1960:96). Another student said, "I was frustrated because the democracy I learned at school was exactly the reverse of what I found in government actions" (97). "We march for democracy and our nation," read a hurriedly prepared placard.

A protest movement developed from the visible gap between what the students' texts described as principles of democracy and what the political authorities practiced under the guise of democracy. Favorable organizational and social conditions prevailed at that time in the students' lives and helped to change their critical consciousness into collective protest. As on campuses in Western countries in the 1960s, Korean students had the tactical freedom and

the ready-made organizations that could be used to mobilize the resources of collective action. The large numbers of students concentrated in university towns were transformed easily into a critical mass for planning and mobilizing demonstrations.

The metropolitan city of Seoul in particular fostered the movement because of its extraordinary number of students. About 80% of the universities, including most of the best, and 60% of all the country's college students were concentrated in that city. It would be comparable to all of Ann Arbor, Berkeley, Cambridge, Madison, and New York were superimposed on Washington, DC. Several elite provincial high schools produced many of the successful students at these leading universities; together they formed dense, hierarchical networks of friendship, and later of leadership, in the movement (K. Kim 1959; B. Oh 1975). The universities were large, with an average of several thousand students at each institution. Often the classes numbered in the hundreds, a situation that made mobilization easy. The position of students in Korean society provided tactical power: they had the institutional resources, the flexible time, and the moral authority to represent the authentic voice of conscience, and their privileged status protected them from harsh punishment by the authorities for their actions.

THE FIRST WAVE OF PROTEST (28 FEBRUARY-19 APRIL)

The protest movement began on 28 February, when hundreds of students from several high schools in Taegu marched into the streets in protest against an unusual directive by the government to attend school on that day, a Sunday. Obviously this directive was intended to discourage youths from showing up at mass rallies held on that day by the major opposition party. No casualties occurred and no arrests were made, but the event inspired further protest movements in other cities. Meanwhile, opposition forces daily resisted the repressive measures employed to "win" the election.

On election day, 15 March, angry citizens of Masan, whose names had been removed mysteriously from the voter registration roster, marched into the city hall asking that voting slips be given to them. Police were called to disperse them. By evening the crowd had grown to several thousand; demonstrators pelted the police with stones and threw back the tear gas canisters that were fired at them. The police brought in fire trucks, but a driver, in a frantic attempt to turn a corner, crashed his truck into an electric pole, triggering a citywide blackout. A jubilant mob battled the police. The police opened fire, killing several youths and injuring many more.[5] The mobs fought back under cover of darkness and ran to the undefended areas of the city, where they destroyed several police stations and government offices.

In Masan the police tortured the arrested individuals indiscriminately, dumped dead bodies into the sea, fabricated evidence, refused to release the identity of those in custody or to state the number of casualties, and framed the whole incident as a communist plot. As a result, fact-finding committees from political parties, major daily newspapers, public interest groups, the National Assembly, and the National Association of Lawyers went to Masan to investigate the incident. The shocking revelations activated public consciousness and

conscience. On 11 April, when a body was discovered in a bay with a police tear gas canister lodged in the left eye socket, citizen unrest in Masan exploded again. As one witness recalled, "Almost every living soul in Masan seemed to have risen to violent hysteria."[6] In battles with the police, 15 persons were killed and 169 were wounded. Several government buildings, police stations, and a notorious politician's house were burned (*Masan Daily*, 17 June, 1960).

After several days of planning, student leaders at the Korea University in Seoul mobilized a major demonstration and led a march of 3,000 students to the National Assembly building. The demonstrators demanded a new, fair election but were answered with few signs of any major political reform. Instead, on their way back to campus, the students were attacked with clubs and chains by hoodlum gangs who later identified themselves as members of the Anti-Communist Youth League, a right-wing organ of the ruling party. On 19 April, the following day, approximately 50,000 students (in a city of 2.5 million persons) fought their way through the police lines and met in front of the principal government buildings in the center of Seoul. These youths were from 30 colleges and high schools, representing almost all of the major universities in Seoul, including Seoul National University.

The government officials were stunned and overwhelmed by the massive upheaval. In the afternoon, police opened fire on the demonstrators in front of the president's office, killing more than 20 persons and injuring many more. This act transformed the protest movement into a major violent rebellion on the day that many people remember as the turning point of the entire episode.

Demonstrations, some peaceful and others violent, occurred spontaneously in Pusan, Taegu, Kwangju, Taejon, and several other cities. In the evening, students and rioters battled the police in a number of cities, killing several policemen and setting fire to major police stations and government buildings. In Seoul and elsewhere, 186 persons were killed and about 1,600 were wounded during the day and night of 19 April. Martial law was declared; on the following day, soldiers took control of the streets of Seoul and four other cities.

THE SECOND WAVE OF PROTEST (20 APRIL-28 APRIL)

For a few days a deceptive calm prevailed in the country; the politicians of the ruling party interpreted this as a sign of impending victory. Yet the use of force on 19 April — indiscriminate and uncontrolled — had seriously undermined the people's trust and transformed the conflict into a revolutionary situation. This new situation made it difficult for the Martial Law Command to use force again. The government s inability to control the massive protest movement by any means other than force shifted the power from the civilians to the military.

Then a leading politician of the ruling party — Vice-President-"elect" Lee Ki-Pung — made the unfortunate announcement that he was "considering resigning." This move was perceived widely as an arrogant manipulation. The military could not and would not support the civilian authority. The top-ranking martial law commanders feared that by successfully controlling the rebellion, they would end up serving the narrow, corrupt interests of the ruling party rather than the national interests. They believed that controlling the rebellion would be possible only by using massive force and probably causing

a civil war. Such an option was viewed as unfeasible and unfathomable in a country that had been devastated by an inconclusive civil war in the recent past.

International pressures, especially from the U.S., intensified during this phase. The U.S. government refused to support repressive measures against protest; this refusal dramatically undermined the legitimacy and effectiveness of the government. The Korean Army, which was subject to the American Military Command in its chain of operational authority, could not provide the regime with the loyalty and logistic support necessary to suppress the forthcoming upheaval.

On 26 April, defying a ban on demonstrations, a group of about 100 university professors in Seoul broke the silence and marched into the streets, loudly demanding Syngman Rhee's resignation. This was one of the first demonstrations of its kind during the entire affair. In the evening, several hundred thousand persons rioted, ransacked the headquarters of the ruling Liberal Party (*Chayudang*), and burned buildings and houses that belonged to notorious politicians. Though brief in duration, the protest was a revolutionary upheaval in spirit and purpose because the intent was to overthrow the regime. Rumor had it that many more hundred thousand persons were planning a major upheaval on the following day. President Rhee resigned the following morning, 27 April, in a desperate move to prevent further bloodshed while a throng of people moved into the streets.[7]

The event is called by various names: the April Revolution (K. Lee 1984), the 4-19 Righteous Uprising, the 4-19 Revolt (Q. Kim 1983), or simply the *Sa-Il-Gu* ("April 19th"). It gave rise to a potent legend of righteous students fighting political corruption as a touchstone of revolutionary movements, and inspired subsequent student radicals to repeat that extraordinary success. The 4-19 Revolt was revolutionary in that it changed in a sudden and violent way the rules, procedures, norms, and principles of the regime, but it was not a revolution. Like the several rebellions that Walton (1984) studied, this revolutionary situation was fully developed but did not progress to the point of coalescing into a unified "alternative polity." The situation fell short of revolution in that the protesters did not claim to be the government.

Unlike the patterns found in classical social revolutions, the revolutionary outcome of the 4-19 Revolt was limited to changes of leadership, policies, and government in the regime without changes in the state and in property relations. The revolt involved mainly urban areas, leaving most of the rural population unaffected. The urban participants, however, included not only students but also a substantial portion of the lower classes, especially the unemployed. Almost half of the 186 casualties, for instance, were college and high school students. The next largest category was the unemployed, constituting about 25%. About 20% belonged to the working class, including day laborers, factory workers, mechanics, and taxi drivers. Several others were listed as clerks, officials, and staff members of political parties. A few were listed as merchants and farmers (*Sa-Il-Gu* Yujokhoe 1971). In Masan, 75% of the wounded were listed as unemployed (*Masan Daily* 1960, 3).

The scale of this revolt is comparable to that of any major revolutionary upheaval in any country. In Seoul alone, the revolt involved almost 100 organizations with 121,850 participants, amounting to 5% of the city's total

population or 18% of the economically active population. This proportion is similar to the level of workers' participation in revolutionary activities during the periods of revolt in France during the 1830s and 1850s (Tilly 1974, 1986, 1989).

In Korean political culture, the 4-19 Revolt is glorified for evincing the spirit of rebellion against injustice and the courage to seek democratic rights and liberties. At the same time, however, it is criticized for a lack of creative vision and for the political disorder it produced. Nonetheless, it remains as a touchstone of Korea s struggle for democracy.

The Process Model

The 4-19 Revolt was a convergence of patterns of protest into a revolt against the regime in what Oberschall (1980) characterized as a "loosely structured collective conflict": "Hundreds of groups and organizations — many of them short-lived, spatially scattered and lacking direct communication, a single organization and a common leadership — episodically [took] part in many different kinds of local collective action" (45). Largely in interaction with authority, such a loosely structured collective protest was transformed into a rebellion: the first wave of protest, followed by violent confrontation between protesters and authority, became a revolutionary upheaval in the second wave. Radical demands were made for the resignation of the President and the end of the regime. A significant segment of the citizens supported these demands, which the rulers and the military became unwilling and unable to suppress.

When we regard conflict as a dynamic process unfolding in a series of stages, our attention is directed to transitions between stages. In particular we may ask why protest escalates to the point where violent coercion comes into play, and why violent coercion increases and raises the level of protest to rebellion. Although the escalation process may be complex and although a full account of its dynamics is beyond the scope of this study, one still can make causal inferences from an analysis based on a process model that distinguishes each of these phenomena conceptually and relates them to one another in a series of interconnected equations.

The process model combines the notion of events and actions as temporally ordered, sequential phenomena with theoretical concepts that organize and transform temporally conditioned factual disorder into a timeless placeless causal structure. This model is based on two major premises. First, causes and consequences are partly contingent on the order of an action or event in an entire sequence of temporally related patterned processes: a single action or event may have different antecedents and effects if it occurs at a different point in one sequence than in another. Actions and events, however, are not discrete, disparate or meaningless pieces of history; they are bound together into a coherent and configured conceptual whole that gives meaning to each of its elements.

Second, the heterogeneous structural conditions to which individuals and groups belong at any time and place influence the probability of widespread participation in collective action. Construction of a process model begins with

identifying a colligated pattern of events and actions in a historical context, translating this pattern into concepts, and arranging the concepts into a time series and a verifiable theoretical form. In short, the model is formulated by interpreting the temporal and spatial relatedness of a historical phenomenon.

This strategy is suitable for a case study of revolt, in which one seeks generalizations about the dynamic process by combining the cross-sectional spatial comparative analysis of variations of local circumstances within a nation with the temporal sequence of events and actions. I analyze the first phase in terms of the theories of the origins of protest, and the second from the perspective of the consequences of violent coercion. I suggest that change of regime is the result of the combined effects of the following three linear regression models, Y_{t1}, Y_{t2}, and Y_{t3}:

$$Y_{t1} = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \epsilon_1$$
$$Y_{t2} = \beta_0 + \beta_1 X_3 + \beta_2 X_4 + \beta_3 Y_{t1} + \epsilon_2$$
$$Y_{t3} = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 Y_{t2} + \epsilon_3$$

where Y_{t1} is *protest* at time 1 (*protest* 1), β_0 is the intercept, β_1, β_2, β_3, and β_4 are parameters to be estimated for the respective variables, X_1 is *economic deprivation*, X_2 is *public opinion*, X_3 is *power difference*, X_4 is *critical resources*, Y_{t2} is *violent coercion*, Yt_3 is *protest* at time 2 (*protest* 2), and ε_1, ε_2, and ε_3 are unknown error terms. I compare variable scores across the units of analysis, 23 cities, for different types of collective action within the recognized periods. The variables are urban characteristics and activities occurring at the city level. Each equation represents a panel for each distinct phase of the process as ordered sequentially.[8]

The main feature of the process model is a series of regression equations in which the dependent variable in one equation becomes one of the independent variables in the next. The dependent-turned-independent variable provides a crucial theoretical link between equations. Such a design, however, may create multicollinearity when the independent variables are highly correlated and when two or more of these variables that show high correlations with the dependent variable are used as independent variables in the next equation. In such a case, the model must be refitted with the data. To minimize collinearity, I opted (among various strategies) to exclude from the subsequent equation the variable that appeared to have the strongest influence on the dependent variable in the earlier equation.

In addition, a process model may suffer from autocorrelation if the dependent variable is time-series data from the same flow of events but is measured separately at two or more different time periods for conceptual and analytical purposes. Earlier protests, for instance, will be correlated with later protests. Note that Y_{t1} (*protest* 1) and Y_{t3} (*protest* 2) are the same protest actions in a continuous flow of events. Protest may generate protest, and the pattern of waves may reveal some particular mechanism that describes the evolution through time. We assume that this may be the case, but the more interesting issue is the extent to which different exogenous factors contribute to the variation of patterns from one stage to the next. Therefore I separate the first phase of protest from the second phase and exclude from equation 3 the impact

of earlier protest. This strategy minimizes autocorrelation and improves the fit between the model and the data.

Protest 1 (Y_{t1}) and *protest 2* (Y_{t3}) occurred at different points in time in relation to the violent coercion, and thus should have different causes and consequences. Each city responds differently not only to the different local characteristics and opportunities but also to the threats and responses by authorities at local and national centers of power. Y_{t1} and Y_{t3} are collective actions; they are different from Y_{t2}, which is violent coercion committed mostly by the agents of the regime. Thus Y_{t2} should have somewhat different causes and consequences. Violent coercion may be a response to protest; this, in turn, produces collective violence as a by-product of groups' capacity for collective action (Snyder 1976; Snyder & Tilly 1972), not particularly as a reaction to public opinion. Violent coercion, however, may either constrain or expand protest movements, depending on public opinion about it. In other words, public opinion may not be directly relevant to explaining the causes of violent coercion, although it may be crucial for explaining the consequences. *Protest 1* is a crucial linkage variable; thus, in equation 2, it is used as one of the independent variables.

In a preliminary analysis, I learned that some variables show high correlations with *protest 1;* accordingly, I excluded one of these variables from equation 2. Equation 3 considers the impact of violent coercion on the second wave of protest in conjunction with the presumed effects of the factors that produced the first wave, but to avoid simultaneity (*protest 2* follows *protest 1* closely), I did not include the effect of the first wave of protest on the second wave. If I had done so, the regression model must have suffered from autocorrelation.

Variables and Measures

Protest is public opposition to the rules and decision-making procedures of a regime, in which objections are expressed openly and collectively. *Protest 1* and *protest 2* are the natural logarithms of the nominal value of the total number of demonstrators per 1,000 economically active persons in the population. Most demonstrations took two or more hours in the course of a day. Unlike strikes, the organizing agency — in the form of a social movement organization — existed only for the duration of the demonstration, although many of these groups emerged from existing schools and represented those institutions. Many demonstrations occurred spontaneously in the streets, largely precipitated by rumors or incidents.

For each city, I summed the number of demonstrators per 1,000 members of the economically active age group for each of the two periods (from 28 February to 19 April and from 20 April to 28 April) and transformed it into logs. Any city during any day in the first period and the second period had an equal distribution of probability of collective action. The pattern of authority, the institutional means of control, and the dominant leadership changed from one period to the other; so did the relationship between coercion and the protest movement. During the first period, the government used violent repression through

national and local police. In this period, it was primarily the national police that tried to control the series of massive demonstrations.

The purpose of measuring the dependent variable in two different contexts is not only to identify the structural origins of protests and to distinguish them from developmental dynamics, but also to estimate the differential structural effects on the distribution of protests, controlling for the effects of violent coercion. This procedure permits more time-oriented causal inference of the effects of violent coercion on the second wave of protest and of the effects of conducive factors in each of the cities on the process of transformation from protest to regime change.

As a measure of *economic deprivation,* I use the unemployment rate as a percentage of the active labor force aged 15-59, as reported by the census. The census defines as unemployed those who are "not gainfully employed" in any occupational sectors including industrial, commercial, and professional fields. Because no unemployment compensation system existed in any form, the index reflects not only the extent of economic deprivation but also the general deterioration of the standard of living across the main economic sectors of urban life. The unemployed do not have organizational resources, and tend to blame themselves rather than others for their own misfortunes. Yet because they have very little stake in the status quo and ample time on their hands, they may cooperate spontaneously and may easily become rebellious when the opportunity of change arises.

Power difference is measured in terms of the difference between the percentage of opposition votes and the percentage of ruling-party votes per city in the 1956 and 1958 elections. The index reflects the extent of opposition to the regime as the degree of support for opposition candidates over the candidates of the ruling party increased during the two national elections preceding 1960.[9]

I measure distribution of *public opinion* by indexing newspaper readership of a certain political orientation. The relationship between newspaper readership and political orientation is reciprocal. The newspapers compete with one another to increase influence and revenues by increasing subscriptions and acquiring advertisers. They report events and editorialize on issues as their imaginary readers would like them to be reported and evaluated. In turn, the readers who already are critical of the government may subscribe to a newspaper that takes positions similar to their own. The two elements rarely match perfectly, but a rough correspondence exists between the sentiments of the public and the circulation of a certain kind of newspaper, whether the paper is critical of the government or favorable toward the opposition. Thus the decision to subscribe to a particular newspaper may represent reinforcement as well as reflection of political predispositions. In this way the leading newspapers cultivate a network of public opinion and foster common attitudes toward prevailing issues. They provide a basis for coherence and unity, among widely scattered potential participants, in collective action and effective mobilization for massive common action.

The press in Korea has a long history as the champion and popular advocate of national and public causes rather than solely as a source of entertainment (Jacobs 1985:53-54). "At least 60 percent of the 42 daily newspapers," observed Robert Oliver (1957), "are anti-government in tone and together

they probably comprise at least 80 percent of the total circulation" (85). Contradictory as it may sound, the freedom of the press to criticize the government existed despite repression by the regime. The major dailies, all concentrated in Seoul, commanded approximately 62% of the total circulation throughout the nation and were decidedly antigovernment. From 1945 to 1960, for instance, the leading opposition newspaper, *Dong-A Ilbo,* devoted 191 of a sample of 401 editorials to evaluating the government's policies. About 60% of these editorials were highly critical (In 1970). A content analysis of another leading opposition newspaper, *Chosun Ilbo,* showed that one of every three editorials published between 1954 and 1960 criticized the government's policies and leaders for violating democratic principles (Cho 1969). *Kyunghyang Shinmun,* until the government suspended its publication in 1959, carried an editorial every other day "to promote a fair election," and criticized the repression and "dictatorship" of the ruling regime. The *Hankuk Ilbo* often printed front-page editorials on issues related to the "democratization of Korean politics." The circulation of the four major dailies reached an estimated total of 500,000, and one of every three households in the major cities subscribed regularly to one of these papers (Ministry of Public Information 1961).

The index of newspaper readership is measured by the percentage of households per city that subscribed to one of the four major dailies in 1960. (The exact month of the survey is not known, but presumably it was conducted in early 1960 by the Ministry of Public Information. The results were kept confidential for several years.) Newspaper readership during this period of Korean history indicates the extent of public opinion critical toward the regime. Unfortunately, no public opinion surveys were held in any comparable form across cities, and we have no day-by-day information from polls about the events during this period. Therefore I use newspaper readership as a proxy for public opinion critical toward the regime during the period under study.

Critical resources are the availability and distribution of manpower necessary for mobilizing collective action. Usually such resources exist in various forms and degrees of organization, formal and informal networks, existing voluntary associations, or groups within institutionalized organizations. The term *critical* performs double duty: it refers to the intellectual preoccupation of a segment of the population with distinguishing right from wrong; at the same time, it denotes a threshold effect of the existence of such a population in mobilizing for collective action. The measure of critical resources is the population of high school and university students as a percentage of all persons aged 16-24. The major premise is that protest is likely to occur and grow where the probability of association is high (Oberschall 1973), and that the probability of collective action will increase as the size of the intellectually critical community increases. Intellectually, students tend to be critical toward the contradiction between the principles they learn in the classroom and the practices they observe in politics. Physically, schools provide ready-made organizational resources for mobilization. The size of the student population in a city affects the probability of protest both directly and indirectly because someone is likely to initiate the movement if many people are present. The decision to initiate protest depends on the expectation that more people will be available to support the cause. At

the same time, the decision to join a movement may depend on the numbers of persons already participating (Granovetter 1978).

Violent coercion includes repressive measures by the government, such as arresting, wounding, and killing demonstrators. It is "the cost of collective action to the contender resulting from interaction with other groups; as a process, any action by another group which raises the contender's cost of collective action" (Tilly 1978:55). In a revolutionary situation where the political language becomes violent, two faces of violence appear: civil violence, composed mostly of property damage, injuries, and deaths, and violent coercion. Violent coercion excludes property damage, injuries, and deaths of agents of authority. The use of such coercion "signals an inability to resolve conflict politically through channels that are regarded as legitimate" (Jackman 1993:158).

The Rhee regime intensified repression of political opposition as the national election approached. As early as 1959, it suspended publication of a major newspaper (*Kyunghyang Shinmun*). Several campaign workers were arrested on nebulous charges in the early months of 1960. During this period, as Scalapino (1961) observed, "the opposition Democratic Party is being intimidated, its leaders threatened, its press restricted, and its general rights violated. The charge of 'treason' is being used loosely to justify these actions" (509). The repression became violent as protests against the electoral fraud spread to several cities, beginning in early March 1960. The police were armed; they opened fire on demonstrators in Masan on 15 March, election day, and later in other cities as well.

I measure violent coercion in two steps. First I take the common logarithm of the number of protesters per city arrested and wounded during demonstrations by the agents of authority between 28 February and 19 April, 1960. The government agents did most of the wounding and killing. The occurrence of deaths in civil strife has a special meaning and provokes strong emotions because the authority, which has an absolute monopoly on force, has violated the trust that it will use its power properly. Therefore, as the second step, I add the actual number of people killed by the government's forces during that period to the logs of the number of persons arrested and wounded per city during the same period. Such a procedure is justifiable because the use of physical force is a crucial index of the survivability of the regime as a legitimate system. Ironic as it may sound, the more frequently the regime resorts to force, the weaker it becomes. The availability of force increases power, but the use of force against protesters undermines that power, especially when the public views the protest as legitimate. I gathered the information from the records of the casualties, collected by the Association of Bereaved Families of the 4-19.

The violent repression that occurred during the first period (28 February-19 April) was reactive coercion. It provoked anxiety and flight in some persons but created anger and aggression in many others. In the second period (20 April-28 April) the government relied on the military for law and order, but the cumulative effects of the use of force (in the first period) and the reluctance of the military to use force (in the second period) created opportunities for a revolutionary upheaval. (Appendix A lists the measures of dependent and independent variables and cites the statistical sources of the data.)

Analysis and Findings

The pattern of protest occurrences and the extent of violent coercion are reported in Figures 1 and 2. The protests occurred in clusters: first around election day against electoral fraud, and then in reaction to the brutal police repression of protesters. A high, positive correlation exists between the scale of mobilization and the magnitude of violent coercion. Violent coercion increased as demonstrations became massive, especially in Masan and other cities where police opened fire on protesters. Citizens rebelled in several cities, especially Masan, where the confrontation was most violent. On 19 April, both demonstrations and casualties reached their highest levels. Violent clashes had a greater impact on the crisis than did nonviolent demonstrations in that the deaths of protesters deepened the meaning of the protest and placed the responsibility for the crisis directly on the nation's leaders. The last phase of the revolt witnessed both a massive upheaval and a large number of casualties across major cities in South Korea.

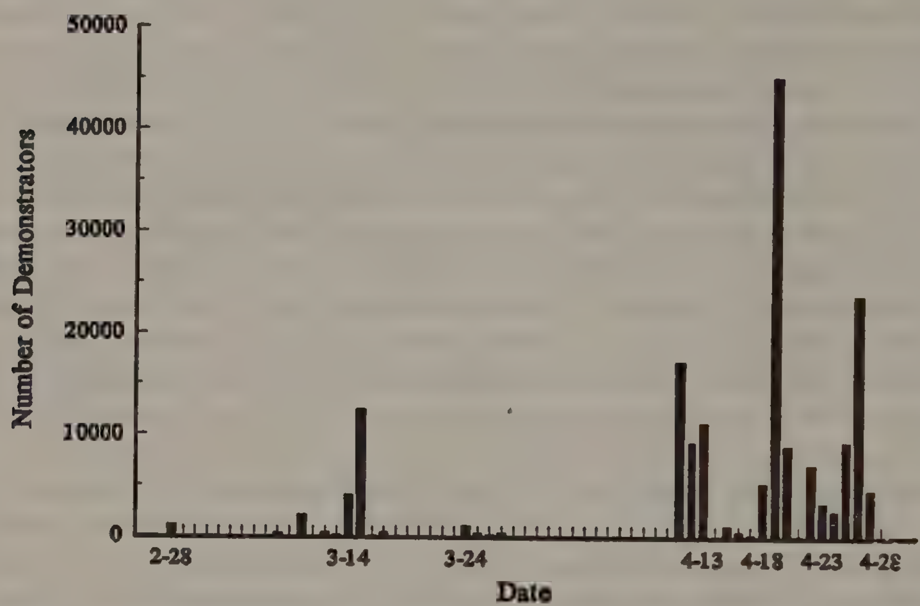
We now assess the effects of indigenous social structure on the origin of the revolt, while considering the effects of earlier protests and violent coercion on later protests. Table 1 shows the ordinary least squares (OLS) unstandardized regression coefficients of the independent variables on *protest 1*, violent coercion, and *protest* 2. (Appendix B presents a correlation matrix of the variables.)

The regression analysis of the *protest 1* model reveals somewhat surprising findings. Contrary to my original expectation, the effect of the history of political contention, as measured by differences between votes for the opposition and for the ruling party, appears to be weak. So does the effect of student population. Also surprising is the negative, weak effect of newspaper readership on the initial stage of the revolt. As displayed in Table 1, column 1, none of the regression coefficients are statistically significant except the relationship between unemployment rate and *protest 1*. A 5% difference in the unemployment rate, for instance, is associated with almost a full unit change in the log of the magnitude of protest, from 100 to 1,000 and from 1,000 to 10,000 on average. It is evident that some opposition vote and a student population are necessary if an initial protest is to occur, but economic deprivation appears to be the preponderant influence.

The finding that economic deprivation alone affects the probability of protest is surprising because it is not compatible with the central argument of the widely accepted resource mobilization perspective. This perspective assumes that the level of deprivation is fairly constant over time and therefore that deprivation would have no significant effect on collective action. But my findings, however, contradict resource mobilization theory and support discontent theory. It appears that extensive unemployment concentrated in urban areas can produce spontaneous cooperation and collective action in the streets. Presumably this reaction is precipitated by some incidents; also and more importantly, it is inspired by political opportunities.

The finding that some opposition vote and a student population, in conjunction with extensive unemployment, may be necessary conditions for protest suggests that discontent can lead to collective action when the balance of power between the opposition and the ruling party changes in favor of the

FIGURE 1: Protest Mobilization in South Korea, 1960



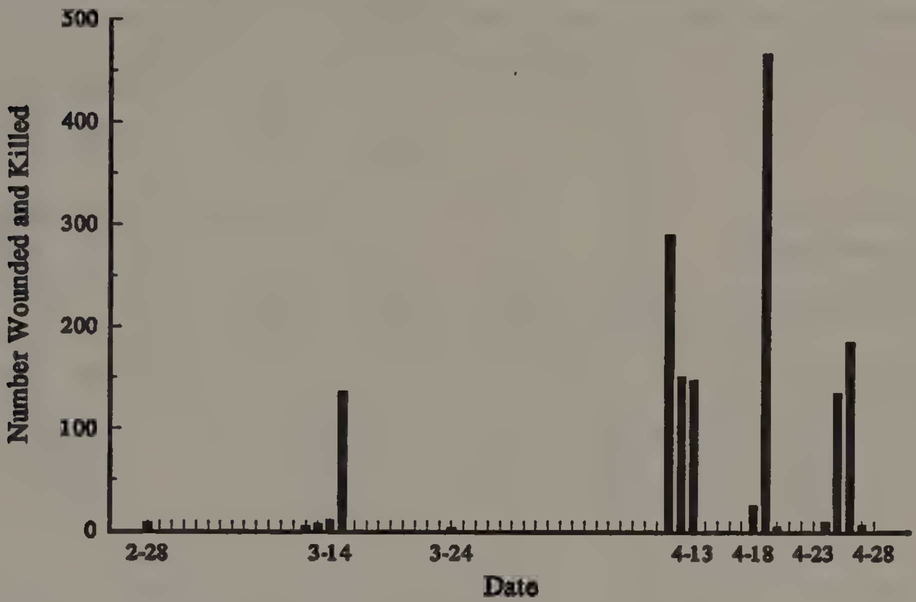
opposition in such a way as to create political opportunities and encourage collective action on the part of the deprived, and when the student population is large enough to be able to launch similar struggles against the regime.

The fit between the model and the data is good enough to create confidence in the robustness of the findings. Regression diagnostics, as indicated by the variance inflation factor ($\sqrt{VIF}$), show no signs of collinearity. The Durbin-Watson *D* statistic shows that the model suffers from no serious autocorrelation. The adjusted R^2 value indicates that the independent variables considered here are important factors in protest. The four independent variables together explain 42% of the variance in the dependent variable during the first wave (adjusted $R^2 = .420$).

The causes and consequences of violent repression are important in understanding the transformation process of protest. The larger the protests, the more likely that they will provoke violent repression. The findings reported in Table 1, column 3 indicate that *protest 1* is the most significant influence on violent coercion. In addition to the size of the protest, student population seems to be crucial in provoking violent repression. Regression diagnostics indicate that none of the independent variables suffer from multicollinearity. The Durbin-Watson *D* statistic indicates that autocorrelation does not exist, thus providing the basis for confidence in the reliability of the estimates.

About 62% of the variance is explained by the three variables included in the model. A large concentration of students (usually in large cities) produced large-scale protests, which escalated into violent confrontations with the police. Two major social groups — the unemployed and the students — seem to have produced different outcomes: the unemployment rate made the difference in the

FIGURE 2: Violent Coercion in South Korea, 1960



overall size of the protest movement, whereas the student population seems to have been decisive in eliciting violent coercion. The violent confrontation between students and the authorities elevated the meaning of protest from local concerns about deprivation to national issues of democracy and justice. Violent repression of students in particular destroyed the legitimacy of the use of force, mobilized public opinion, and galvanized national opposition to the regime.

Protest that occurs in the context of political conflict at the national level is likely to trigger further protests. Protest generates protest and becomes a revolutionary upheaval as the interaction between protesters and the authorities grows violent. During the first period of crisis (28 February-19 April), the government used intermittent but violent repressive measures on students and other citizens in Taegu, Masan, Seoul, and several other cities. Such inconsistency of coercion tends to inspire more protest in some cases and less in others. Protests occurred in the second period (20-28 April) in cities where they had been staged in the first period. These differences in the pace and magnitude of protest may be attributable in part to the effectiveness or, ironically, the ineffectiveness of coercion. The factor that makes coercion most ineffective and thus inspires more protest seems to be the combination of extensive violence and public opinion critical toward the regime.

One of the most striking findings of our study is that violent coercion changes protest movements into revolutionary movements. As reported in Table 1, column 5, only newspaper readership and violent coercion appear to be statistically significant at .01 level. The effects of unemployment rate and opposition vote on *protest* 2 are not significant. These selected variables together explain approximately 65% of the variance in *protest* 2, revolutionary upheaval. The model seems to fit the data well. Regression diagnostics reveal no indications of autocorrelation or multicollinearity; thus the estimators appear reliable.

TABLE 1: Ordinary Least Squares Regression Analysis for Protest 1, Violent Coercion, and Protest 2

* $p < .05$ ** $p < .01$ (two-tailed test)

The findings suggest that transition from protest to revolutionary upheaval is spurred by mobilization of public opinion critical toward violent coercion. Violent coercion tends to escalate protest in cities where public opinion critical toward the regime already exists to a substantial degree. In other words, public opinion seems to have as much impact on the transition from protest to revolutionary upheaval as does violent coercion.

Newspaper readership seems to transform protest into revolutionary upheaval by politicizing, moralizing, and condemning violent confrontation between the authorities and the protesters. By simply reporting the news, newspapers tend to enlarge the network of potential participants; by evaluating what the government did or should not have done, they draw the battle lines; and they elevate local concerns into national issues, unify protest movements with similar purposes, and characterize the movement in a way that is more meaningful and larger than life. By taking a broad national perspective, the newspapers expose the contradictions between democratic constitutionalism and authoritarian practices and condemn the narrow political interests of the regime, against which very few elites can find a justifiable defense.

Violent coercion seems to have exactly the opposite effect to what was intended, namely increasing the power of the regime. It dramatically exposes the authoritarian power behind the thin veil of democracy and undermines the moral legitimacy of the regime. More important, violent coercion seems to divide the elites from within — separating the "mild" from the "tough" faction — and thus makes it difficult for the regime to act effectively. Therefore, ineffective and indiscriminate coercion provokes revolutionary upheaval. The government's resorting to indiscriminate violence destroys the system of legal-

rational authority and provides the opposition with a license to commit violence; it invites eruption not only by the unemployed or students but also by substantial portions of other segments of the urban population. At this point the protest becomes a revolutionary upheaval because the issues of discontent, violence, and law and order are now politically and ideologically charged as the result of misrule.

Discussion and Conclusion

This study provides substantial evidence that protest begins with economic deprivation and is transformed into revolutionary upheaval not only because of violent coercion but also because of generally critical public opinion regarding the government. Regression analysis of data that rely on the characteristics of local social structures rather than on national stimuli supports the thesis that a regime changes when economic deprivation is followed by violent coercion and by mobilization of critical public opinion.

We must recognize the limits of regression analysis and of the ability to draw conclusions about the dynamics of revolt at the national level by analyzing variations in local conditions. Our findings must be evaluated in terms of the context of the time and the national setting. In understanding the connection between economic deprivation and protest, we must take into consideration the national atmosphere in South Korea in 1960; This atmosphere was charged politically by the overall climate of prospects for change, by the approaching elections, and by the widely publicized fear of electoral fraud. When we consider these national circumstances, it is not hard to understand the effect of economic deprivation on protest.

To be sure, as is commonly observed, the unemployed may suffer a high level of deprivation, but they have little propensity to protest. Although they have time on their hands and resent their situation acutely, these "resources" do not easily produce an organized revolt because of a "pathology" that paralyzes them and prevents them from acting together (Horwitz 1984). The economically deprived blame themselves for their misfortune, isolate themselves from the rest of the society, are unwilling to treat private difficulties as a public issue, and are ambivalent toward authority. Pervasive unemployment in major cities, however, is more likely to transform private misfortunes into a public issue and also to justify protest when the political opportunities change.

The national electoral sentiment in the late 1950s was turning decisively against the regime. While the rural areas remained under the influence of the ruling party, the cities became the bastion of opposition. Eighteen of 23 cities voted consistently for the opposition candidates during the 1956 and 1958 elections; only five showed some support for the government candidates. No direct connection exists between support for the opposition and the subsequent protest movement, but it was in this political climate — increasing opposition to the regime — that widespread grievances found political expression. In short, economic deprivation becomes a factor in the emergence of protest when it is so extensive and so highly politicized that individual miseries become a public, political issue for which the existing government is viewed as responsible.

In addition, support for the opposition party at the local level is a weak predictor of protest. It shows only negligible influence on the initial stage of revolt and exerts no direct influence on the revolutionary phase of the movement when the other independent variables are held constant. This finding seems to reflect the fact that the opposition parties were not strongly in opposition. These parties were defending their own interests and those of a few political groups rather than broad class interests. The main opposition party, *Minjudang*, was conservative in its policies and deliberately avoided identifying with the main forces of protest for fear of inciting a full-scale revolution. At the same time, as many demonstrators announced in public on various occasions, the protest was against the regime, not for the opposition party.

When we examine protest in the context of national movements, however, we may find that the general political circumstances and the sense of solidarity in opposition to the regime, nurtured by the national desire for change, made an important contribution to the origins and dynamics of protest movements. Just as subscribing to a newspaper with a certain orientation binds the readers into a symbolic community of political opinion (Alexander 1988), a history of similar voting patterns in different places at the national level makes it easier for potential organizers and participants to initiate protest because they believe that their call for change will be answered by persons in other cities.

One of the most important institutional features of the time that helps us understand the findings is the Rhee regime's authoritarian and repressive nature. An authoritarian regime cannot survive massive protest movements without intensifying its repression and a repressive regime often collapses at a point when the effectiveness of repression reaches a certain threshold of not being able to exercise its coercion on the citizens. A democratic state is stronger than an authoritarian regime because it has a broad basis of support from the people. An authoritarian regime usually has a very narrow basis of support and when the opposition to it becomes widespread, it is doomed to collapse. As the size of the opposition grows, the legitimacy of the opposition also gains root. In the post-war period in South Korea, an irreversible political trend developed under the structural influence of political authoritarianism and economic stagnation. The more the repression became intensified, the more widespread the opposition to the regime grew in the years prior to the upheaval.

In the case of the 4-19 Revolt, a concatenation of special circumstances produced a critical situation: a high concentration of the unemployed and students and of potential participants and supporters in major cities, especially Seoul, the capital city; unity among the major elements of the political opposition; and critical public opinion.

Because of the catastrophe caused by the Korean War, the government was fiscally bankrupt and poorly prepared for the massive upheaval. It became morally bankrupt and could not defend its position under the mantle of law and order when it succeeded in stealing an election while drawing its legitimacy from democratic, constitutional principles. The U.S. government promoted democracy abroad, especially among dependent states such as South Korea, but was embarrassed by the blatant disregard for democracy on the part of Rhee and his party leaders. The Eisenhower administration condemned the rigging and blamed the leaders of South Korea for their failure to take responsibility for

the misrule. The timely announcement of condemnation encouraged the opposition forces to demand President Rhee's resignation. Therefore, when students, intellectuals, and university professors — including some famous nationalists — took the lead in protesting, the government could not define the dissidents as criminals or frame them as communists and thus crush the movement by legal-rational authority.

The leadership of the movement by students in elite universities legitimated the revolt, and the mass media championed the cause of protest. The authorities found it difficult to control the revolt because the protesting groups were diverse, disconnected, complex, and large, without a unified command. If a single national leadership had existed, the authorities could have destroyed it easily. As if shooting in the dark, however, the elites responded to the protest in an indiscriminate, incoherent, and unusually harsh manner. This combination of harshness of policy and weakness of legitimacy allowed the protest movement to become an open rebellion against the regime. In fact, ironic as it may seem, the government could not control the rebellion by force because it used force and thus undermined its own legitimacy.

Violent coercion, especially reactive rather than proactive coercion, transforms protest into revolutionary upheaval. Violent coercion, when exercised extensively and preemptively, may deter protest and the expansion of protest. Insufficiently intense coercion, however, when exercised in reaction to protest may be ineffective. Violent coercion becomes counterproductive when the elites are divided among themselves about the use of such coercion and when the protest against which it is intended gains popular support. Furthermore, coercion exposes the contradictions between the principles and the practices of the regime in an authoritarian state. A movement becomes revolutionary by breaking down the coercive power, or by making it difficult for the elite to use force in controlling the movement, because the elite has destroyed the moral legitimacy of the use of force.

By forcing the leaders out of power, the 4-19 Revolt destroyed the rules and procedures of the authoritarian regime. In doing so, it revived the principles and norms of the state from which the regime drew its legitimacy, and opened the way for democracy.

This study offers a theoretical model that suggests that protest movements develop into revolutionary movements that forces a change of regime when protest occurs under conditions of extensive urban unemployment combined with a history of opposition to the regime. The regime will collapse under such a pressure when it uses coercion against the movement that is based on a widespread critical public opinion. Insofar as these conditions interact in such a way as to politicize economic deprivation, to increase participation of citizens across different cities, and to increase legitimacy of the opposition while undermining the legitimacy and effectiveness of the use of coercive force, then the repressive and authoritarian regime will collapse. Such a model may not fit political processes of change of regime across different cultures and historical periods. Different structural conditions produce different varieties of change of regime. However, the historical conjunctures and specific circumstances associated with change of regime discovered here developed from political conditions and trends similar to those one can commonly observe in many of

the developing societies in the contemporary world. As a research question, why some regimes change under similar conditions while others do not presents a challenge to all students of protest and revolutionary movements.

Notes

1. The event that we study can be defined broadly not as revolution but as revolt. In revolution, the transfer of power as an outcome of a revolutionary situation is more extensive than in revolt. Protest becomes a revolutionary movement, a revolutionary upheaval or a rebellion as the demand for change shifts from issues related to policies and procedures to issues concerning principles, norms, and leadership of the regime (Tilly 1978, 1993). Hibbs (1973), Gurr (1980), and Gurr and Lichbach (1986) distinguish protest from rebellion for analytical purposes and find in cross-national comparisons that these events have different causes and consequences.

The distinction between protest and revolutionary upheaval or rebellion that I use here is similar to that proposed by Jenkins and Schock (1992): "Social protests [are] aimed at limited issues such as changing the policies of authorities or particular personnel; and rebellions [deal] with fundamental issues such as who governs and what is the structure of authority" (162). For more extensive definitions of protest, see Eckstein (1989: xi) and Lofland (1985:1-2). For broader definitions of revolution, see Skocpol (1979:4). I use the terms, *revolutionary movements, revolutionary upheaval,* and *rebellion* interchangeably to describe collective actions in revolutionary situations.

2. Deprivation as a social condition has both synchronic and diachronic implications; thus deprivation, by definition, is relative to time (Davies 1962) and to a comparative frame of reference (Gurr 1970). Though deprivation is common and widespread throughout much of human experience, it is not constant but varies according to time and place; thus relevant to an explanation of collective protest.

3. Results from cross-national studies, however, are generally weak for this contention and are inconclusive at best (see Gurr & Duvall 1973; Hibbs 1973; Zimmermann 1980).

4. Reported by *Dong-A Ilbo* (3-20 March, 1960) and documented later by *The History of the Korean Revolutionary Trials* (Korean Government 1962).

5. According to a subsequent report, seven persons were killed and 72 were injured (see J. Oh 1968:61).

6. Interview with Chong-Sik Chong on 22 June, 1960 (in D. Kim & Ahn 1960).

7. Syngman Rhee left Korea in May for Hawaii, where he died in exile in fall 1963. An interim government under Ho Chong conducted a new election for the National Assembly, from which Chang Myon emerged as the leader. Unable to institutionalize political power (Han 1974), Chang Myon succumbed in May 1961 to a military *coup d'etat* led by General Park Chong-Hee.

8. This strategy is similar to what Snyder (1976) called "event linkage," whereby one attempts to predict the characteristics of one event from the characteristics of the previous events.

9. The strength of opposition to the regime also can be gauged by a proportional measure — for instance, by dividing the percentage of the opposition vote by the percentage of the vote for the ruling party. This measure, however, overestimates the extent of dominance by the opposition and underestimates the support for the ruling party. For example, the index will be .111 in a city where the vote is 10% for the opposition and 90% for the ruling party, 1.00 when the vote is divided evenly, and 9.00 when the pattern is reversed, with 90% for the opposition and 10% for the ruling party. Because I am more interested in measuring the pattern of power difference than of power dominance, I subtract the vote for the ruling party from the opposition vote. This measure reflects the extent of power difference equally for the opposition and the ruling party. In any case, the measure of difference is correlated highly with the measure of dominance ($r = .997$) in this study.

APPENDIX A: Cities and Measures Used for Analysis[a]

City	(1) Protest 1 (Log)	(2) Violent Coercion	(3) Protest 2 (Log)	(4) Unemploy-ment Rate (%)	(5) Newspaper Reader-ship (%)	(6) Opposi-tion Vote (%)	(7) Student Population (%)

Nonconformity in Competitive Repertoires: A Sociological View of Markets*

DANNY MILLER, *École des Hautes Études Commerciales, Montreal and Columbia University*
MING-JER CHEN, *Columbia University*

Abstract

A sociological framework is proposed for studying nonconformity in competitive repertoires. We argue that the extensiveness and continuity of a company's market interactions very much influence its level of nonconformity. Market-level factors that might influence nonconformity include customer and competitor diversity and the continuity of traditions; and firm-level factors include the size, resources, and industry experience of an organization. Nonconformity may also be driven by economic factors such as market growth and financial returns. Most of these sources of nonconformity were confirmed in a study of the competitive repertoires of the major U.S. airlines. The findings also show that competitive nonconformity was associated with subsequent declines in financial performance, but mainly for smaller airlines with homogeneous markets. This study supported some central notions from the sociology of markets and, with qualification, from institutional theory.

Some organizations are conformists. They compete in conventional ways and act much like their competitors. Others are iconoclasts and adopt competitive practices that deviate from industry norms. This study looks into some of the factors that underlie this nonconformity. Although we examine economic sources of nonconformity, we will pay particular attention to those influences suggested by the sociology of organizations, markets, and networks, viewpoints that have been largely ignored by scholars of competitive strategy.

The issue of nonconformity could well prove important. Companies deviating from conventional modes of competition may surprise their rivals (Chen & MacMillan 1992), develop appeals that are distinctive and enduring (Porter 1985; Prahalad & Hamel 1990), and be difficult to imitate and retaliate

against (Chen & Miller 1994). But nonconformists may fail to supply customers with the products or services that they have come to expect. Indeed, some institutional sociologists have argued that nonconformity can erode organizational legitimacy as perceived by clients and regulators (DiMaggio & Powell 1991; Scott 1987). Also, unconventional rivalry may risk evoking hostile reactions from competitors (Chen & Miller 1994).

Scope of the Study

This study compares "conventional" or isomorphic competitive repertoires to "nonconformist" ones that depart more markedly from industry central tendencies or de facto norms. Competitive repertoires consist of the entire set of market-oriented actions used by individual firms to attract customers and cope with rivals (Miller & Chen 1994). These actions may include price changes, new product and service introductions, and geographic expansions. Conventional repertoires employ a mix of actions typical to firms of similar scope and scale in the same industry. Nonconformist repertoires, on the other hand, encompass a set of actions that are atypical — that emphasize market-oriented ploys rarely used by competitors or that avoid actions frequently used by rivals.

Conventional or isomorphic behavior has been of great interest to institutional sociologists, some of whom view conformity as an important way for organizations to gain legitimacy and cooperation from regulators, competitors, and even customers (Powell 1991; Scott 1987). Conformity has also been of central concern to sociologists studying the emergence and diffusion of practices and norms in groups, networks, and markets (Burt 1987; Granovetter 1985). In using the sociological literature to derive our framework, we take as our point of departure White's (1981) dictum that markets are "social structures among specific cliques of firms and other actors who evolve roles from observations of each other's behavior. [What] a firm does in a market is to watch the competition in terms of observables" (518). Indeed, the thesis of this study is that market conformity and nonconformity in the competitive repertoires of organizations can best be analyzed from a sociological perspective that departs fundamentally from economic approaches to business strategy. More specifically, we will argue that *nonconformity will be very much a product of an organization's social context and its interactions with and relationship to that context.*

The focus of this study, however, will differ from most of the earlier sociological literature. First, as indicated above, we examine the entire repertoire of a company's market-oriented competitive actions, not just the unitary rituals or administrative adoptions that are the typical foci of most studies (Burt 1987; Zucker 1987). Second, we do not posit any a priori norms of tactical conduct, since they are absent, unclear, or ephemeral in most competitive markets (Levine 1987). Instead, our concern is with de facto norms — that is, with patterns of competitive behavior that are typical of a group of interacting competitors of similar market scope. Nonconformity can be assessed relative to such typical behavior. Third, we do not view conformity or nonconformity as an imperative, equilibrium condition, or binary choice, but rather as a continuum along which competitors range widely. Fourth, our model incorporates

economic as well as sociological sources of nonconformity. This is done to arrive at a more complete predictive model and to show the complementarities among approaches. Finally, we assess the financial implications of competitive nonconformity at the organizational level. These traditionally have been of more concern to economists and strategy theorists than to sociologists (Mezias 1990; Oliver 1988).

Sources of Competitive Nonconformity

A FRAMEWORK FOR STUDYING COMPETITIVE NONCONFORMITY

It has been suggested that organizations often gravitate toward administrative isomorphism (Fligstein 1985; Haveman 1993b; Palmer, Jennings & Zhou 1993; Spender 1989). Convergence upon a "conventional" competitive repertoire may be common as well. When geographic expansion becomes popular in an industry, some executives feel obliged to get into the act (Fligstein 1985; Spender 1989). Where price cutting is common, many managers are induced to respond in like fashion (Chen 1988). Scholars of business strategy have attributed mostly rational economic motives to such behavior (Porter 1980, 1985; Rumelt, Schendel & Teece 1991). And although we do not rule out such motives, we believe that they are very much conditioned by an actor's social relationships (Granovetter 1985; White 1981, 1988). More specifically, the extensiveness and continuity of interaction of an organization with other actors in its market will help explain its conformity to de facto industry norms.

The social context of an organization can have a great impact on conformity. Some contexts, for example, encourage *extensive* interaction: that is, diverse relationships with a wide variety of actors. Such interactions expose members to diverse perspectives, encourage independent thought, and are quite conducive to nonconformity (Granovetter 1973, 1985). Other contexts, by contrast, are characterized by contacts with a rather homogeneous group of actors. The social cohesion of such homogeneous environments typically exerts strong pressures for conformity (Burt 1987; Homans 1950).

Another important aspect of the context that bears on nonconformity is the *continuity* or duration of traditions. Some contexts are in a state of upheaval and have not yet settled down enough to allow the emergence of norms. Others are more established and imbued with tradition. Clearly, nonconformity will be strongest where norms have not yet been firmly established (Erickson 1988; Homans 1950).

Nonconformity, of course, is not simply a function of an organization's social context but also its links to, dependencies on, and embeddedness within that context. And again the extensiveness and continuity of interaction play important roles. Large firms typically have extensive dealings with a great many kinds of rivals and customers, some of whom do things rather unconventionally, and none of whom the giants are much dependent upon. Many large firms thus have the broad experience, the freedom, and the resources to deviate from industry norms (Haveman 1993a). Smaller firms, on the other hand, are more likely to find themselves interacting with a few similar actors upon whom they

depend a great deal. Convention is hard to ignore under these conditions (DiMaggio & Powell 1983, 1991; Granovetter 1985).

If the continuity of industry traditions encourages conformity at the market level, then the continuity of industry experience plays a socializing role at the firm level. Older, experienced companies are likely to have been more thoroughly exposed to and influenced by industry traditions than are new entrants to an industry (Meyer & Zucker 1989). This will dampen their nonconformity.

As important as these social factors are, we expect them to be complemented by two key economic considerations. Specifically, the lure of opportunities and the threat of poor returns may cause companies to move away from conventional modes of competing (Porter 1980:215-35; Scherer 1980:407-58; Schumpeter 1950). At the market level, some of these influences may take the form of growth possibilities, and at the firm level, they may appear as lapses in financial performance.

The sources of nonconformity are arrayed in Table 1.

THE SOCIAL CONTEXT

The impact of group norms as well as an actor's ability to entertain possibilities that extend beyond those norms will be influenced by the continuity and extensiveness of social interaction. These conditions are, in part, a function of the market context within which a firm operates: industry traditions and the diversity of markets being especially important.

The Diversity of Markets

The perceived realities of administrators are very much influenced by their interactions with their environments. The originality of managerial viewpoints will depend in part on whether firms have most of their relationships with a small group of actors — that is, customers and competitors — or whether they spread these relationships more broadly (Berger & Luckmann 1967; Scott 1987). Burt (1987) and Erickson (1988) suggest that actors are more likely to conform if they depend on a tightly networked clique of similar others. Conversely, "the socializing influence of cohesive ties within a clique can be eliminated by conflicting ties outside the clique" (Burt 1987:1293). Indeed, Granovetter (1973) shows there to be an inverse relationship between the intensity and extensiveness of relationships: actors with very intensive ties to a few parties tend not to have very extensive ties, and vice versa. In any event, extensive and diverse interactions may dampen the salience of norms and encourage nonconformity.

Certainly, these observations may apply to two central aspects of a market environment: diversity in the set of competitors and diversity in the set of customers. Firms that compete against many different rivals for numerous market niches are apt to receive more unconventional ideas for competing than firms that interact with a more homogeneous set of contacts (Burt 1987; Erickson 1988). The former are exposed to a wider variety of competitive challenges that inform them of unorthodox ways of conducting business (Miller 1993; Miller & Chen 1993). A diverse set of customers is also likely to generate demands for unusual services and hence for nonconformity.

TABLE 1: Sources of Nonconformity

	Extensiveness of Interaction	Continuity of Interaction	Economic Motivations
Social context (market level)	Customer and competitor diversity	Absence of industry traditions	Market growth
Links with context (firm level)	Firm size and resources	Firm inexperience	Poor returns

Companies that compete for the same customers and niches of the environment are dependent for resources and acceptance on a relatively small group of actors (rivals, clients, institutions), and so are quite susceptible to pressures from them to conform (Homans 1950; Pfeffer & Salancik 1978; Powell 1991). By contrast, organizations with more extensive interactions and a vaster market scope may be sufficiently independent to resist such pressures (Scott & Meyer 1987).

Hypothesis 1. Competitive nonconformity will be positively related to the diversity of a firm's competitors and customers.

Industry Traditions: The Time since Market Upheaval

Erickson (1988) and Homans (1950) showed that conformity increased with the continuity and stability of contact among group members. By contrast, an absence of continuity or experience in interaction, as prevails in very young industries or during periods of upheaval, precludes convention and tradition, and thus provides the latitude for nonconformity (DiMaggio 1991; DiMaggio & Powell 1991; Granovetter 1985).

In new industries or in those undergoing a thorough upheaval, there are no established rules of the game (Boeker 1989; Powell 1985; Tushman & Anderson 1988). A heterogeneous mix of competitive strategies are conducted as firms collectively grope their way toward a viable approach. Here there are few norms or traditions to serve as guides and few customer expectations or standards with which to comply (Mezias 1990). But in time, implicit norms and conventions develop. Firms begin to conform to certain "accepted" ways of competing (DiMaggio 1991; DiMaggio & Powell 1983; Spender 1989). The passage of time, in other words, brings with it mutual mimesis and the mantle of tradition (DiMaggio 1991; Fligstein 1985; Palmer, Jennings & Zhou 1993; Powell 1985).

Hypothesis 2. Competitive nonconformity will be negatively related to the time since the last major industry upheaval.

AN ORGANIZATION'S LINKS TO THE SOCIAL CONTEXT

Although the social context can have a profound impact on competitive nonconformity, a given firm's dependence upon and embeddedness within that context may be important as well. The size and resources of a company, for example, may give it the extensive experience and the means to enjoy considerable independence from the pack. Conversely, the age of an organization may reflect the depth of its exposure to the socializing forces of industry tradition.

Firm Size and Slack Resources

The role of company size and resources in stimulating originality seems to pull in opposite directions. On the one hand, large and rich organizations typically are exposed to many different ways of competing (Burt 1987). Also, their scale makes them less dependent and thus less susceptible to the conforming influences of a few key relationships (Granovetter 1973). Many such large enterprises can afford to take risks and stray from convention (Haveman 1993a). And their slack resources may fund the development of more elaborate and original repertoires (Cohen & Levinthal 1990). Moreover, large and wealthy firms may be able to buffer themselves from external threats (Pfeffer & Salancik 1978) and avoid complying with industry norms (Mezias 1990).

On the other hand, many institutional and bureaucratic theorists would argue that size and resources have a dampening effect on nonconformity. Some large organizations adhere to convention simply because they are so visible to — or so closely monitored by — regulators (Cooper, Willard & Woo 1986; Jacobs, Useem & Zald 1991; Powell 1991; Zelditch & Walker 1984; Zucker 1987). Size may also encourage bureaucracy and inertia (Hannan & Freeman 1984; Haveman 1993a). Smallness, by contrast, forces some companies to be original, since they have not the resources to vie with their larger rivals using conventional approaches.

Conflicts between network and resource dependency views on the one hand, and institutional and bureaucratic arguments on the other, highlight the tentativeness of the following hypothesis. However, in industries like the one we have studied, big and small firms face similar regulatory scrutiny, and considerable resources are needed for many kinds of originality. Under these circumstances we tend to favor the network and resource dependency arguments.

Hypothesis 3. Competitive nonconformity will be positively related to the size of the firm and its level of slack resources.

Firm Age

If, as we have argued, industry traditions can generate conformity, then so can a firm's continuity of exposure to those traditions. This, in part, is determined by the age of an organization (Aldrich & Auster 1986; Miller 1993; Tushman & Romanelli 1985). Organizations that have long been exposed to typical industry practices and norms are that much more likely to be influenced by them. Meyer & Zucker (1989) argued that well-established organizations develop such stable ties to other institutions, businesses, and regulatory bodies that their ability to stray from contemporary norms is limited. These alliances buffer and protect

firms from external challenges, thereby making nonconformity still less likely (Burt 1987; Granovetter 1973). Young firms, by contrast, are more apt to be nonconformists, in part because of their lack of experience with industry traditions and in part because of their rather modest institutional attachments (Baum & Oliver 1992; Stinchcombe 1965).

As corporations get older, they also become wed to traditional ways of doing things, to more automatic forms of behavior, and to learning that refines conventional approaches instead of developing original ones (March 1991; Starbuck 1983). Anything unorthodox is viewed with suspicion as being too risky or as negating cherished traditions. Deviations are also seen to challenge the past contributions of those in power (Staw 1981).

Hypothesis 4. Competitive nonconformity will be negatively related to the age of the firm.

ECONOMIC INCENTIVES FOR NONCONFORMITY

So far we have discussed purely sociological determinants of nonconformity. But there are at least two major economic incentives for nonconformity: the pursuit of growth opportunities and the avoidance of poor returns. As we shall see, however, even these economic considerations are best understood within their social contexts.

Market Growth

Managers are apt to depart from traditional ways of doing things during periods of environmental expansion — when the growth of an industry or the emergence of new market niches encourage unorthodox means of capturing additional business. During periods of rapid growth, companies experiment with a variety of techniques to appeal to the burgeoning army of potential customers (Chandler 1962; Scherer 1980; Tushman & Anderson 1988). Moreover, the new rivals and customers that enter markets during periods of growth may erode competitive conventions and elicit unorthodox new methods (Porter 1980:215-33; Schumpeter 1950). Rapid market growth also fosters managerial confidence that can again motivate departures from convention. The blossoming years of the semiconductor industry provides a good example of such competitive creativity (Eisenhardt 1989).

Eras of slow growth or stagnation, by contrast, often encourage competitive isomorphism. An unchanging stock of customers and rivals allows conventional wisdom to dominate (DiMaggio 1991; Zucker 1987). Moreover, in stagnating contexts there is little incentive to chase after customers using unconventional approaches as there is not much new business to be had. Stagnant contexts are also pervaded by a shortage of resources, which renders firms more susceptible to the economic and institutional pressures imposed by powerful stakeholders (DiMaggio & Powell 1983, 1991; Pfeffer & Salancik 1978:39-52). And because corporate conservatism often accompanies a downturn, expensive forms of nonconformity are discouraged.[1]

Hypothesis 5. Competitive nonconformity will be positively related to market growth.

A Firm's Poor Performance

In light of the above it is perhaps paradoxical that threat can be as great a stimulus for nonconformity as market opportunity. Yet scholars of organizations note that companies — the majority of whom, by definition, follow conventional repertoires — are likely to abandon conventional repertoires mainly under pressure of necessity. Abysmal returns to capital are great incentives to search for novel remedies (Amburgey & Miner 1992; Cyert & March 1963). Poor performance, at least in the majority of firms that are conforming, motivates managers to try something less orthodox (Lant & Montgomery 1987; Starbuck, Greve & Hedberg 1978). Even the literature on prospect theory argues that the propensity to take risks — and therefore, perhaps, to be deviant — increases in the domain of losses (Tversky & Kahneman 1973).

Good performance, on the other hand, fosters complacency and encourages managers to take the path of least resistance (Miller 1993; Milliken & Lant 1991). According to institutional and bureaucratic scholars, this attitude, more often than not, means sticking with standard, "tried and true" industry recipes (Lant & Montgomery 1987; Spender 1989). Nonconformist strategies are often risky, they are difficult to devise, and they may induce political resistance from inside and outside an organization (Scott 1987). Hence they are unlikely to be used by successful firms whose managers are not being pressured to undertake such tribulations. Heterodoxy, in short, typically demands greater incentives than conformity.[2]

Hypothesis 6. Competitive nonconformity will be negatively related to prior organizational performance.

The Hazards of Nonconformity

Competitive nonconformity, we expect, will usually hurt financial performance because it increases costs and competitive risks and reduces the acceptability of organizational actions. Moreover, nonconformity will be especially inappropriate to small firms operating in undiversified markets as risks of failure there are high. Large organizations, on the other hand, may have the resources to make deviant repertoires acceptable to their customers; and diversified firms may be able to reduce the risks of nonconformity and use it to good advantage in those of their markets that depart from industry norms.

The strategy/industrial economics literature and the writings on institutional sociology seem to be at odds over the implications of competitive nonconformity. Porter (1980, 1985) has espoused the merits of distinctive (hence nonconformist) competitive repertoires that hit rivals where they are weakest. For example, he suggests differentiating products by constant quality or image improvements or developing unique cost advantages that allow frequent price-cutting. And indeed some such unconventional tactics have the advantage of being difficult to imitate (Lieberman & Montgomery 1988). Others are hard for competitors to detect and respond to because they are stealthy (Chen & MacMillan 1992; Chen & Miller 1994). And still others enable firms to develop

distinctive resources and competitive advantages (Porter 1985:120-64; Prahalad & Hamel 1990). But nonconformity in and of itself is unlikely to generate economic rents unless it meets the needs of customers and the challenges of competitors. And therein lies its major difficulty. Unique products and processes may do more to scare off customers and stir up rivals than to reduce the firm's vulnerability.

Thus the dangers of nonconformity may well outweigh its advantages. The defiance of convention often carries with it hazards of novelty and unpredictability, the possibility of attracting attention from aggressive imitators, and the elevated costs of convincing customers of the advantages and legitimacy of an unusual approach (Kreps 1990; Shamsie 1989; Wernerfelt & Karnani 1987).

Institutional theorists, in particular, have argued for the advantages of conformity in many organizational contexts. They believe that companies stand to benefit by following typical repertoires, as these are perceived as attractive and legitimate by customers, competitors, and powerful stakeholders alike (Meyer & Rowan 1977; Scott & Meyer 1983). Thus, although we have argued that poor performance will promote nonconformity, we also expect that nonconformity itself will tend to generate decreases in performance.

Hypothesis 7. Competitive nonconformity will erode financial performance.

Certainly hypothesis 7 is a very general one that demands some specification of contexts. Competitive deviation is less likely to erode performance in large organizations that can much more easily support or legitimize their unorthodox activities (Haveman 1993b; Scott & Meyer 1987). Big firms have the visibility and market presence to generate acceptance for their new approach, the power to lobby government agencies, and the influence to ally themselves with partners who can help them indoctrinate customers (Mezias 1990; Miller 1990). Hence some giants can successfully resist — and ultimately transform — industry norms and conventions. But smaller organizations may be too poor and powerless to diverge from the pack (Haveman 1993a). Their relative obscurity and lack of resources make it less likely that their nonconformity will attract profitable trade.

Hypothesis 8. Competitive nonconformity is more apt to erode performance in small than in large firms. (That is, size will moderate the relationship between deviation and change in performance.)

Another potential moderator of the relationship between nonconformity and change in performance is the diversity of markets a firm faces. Target markets that are diverse will usually include at least some niches whose customers have unusual demands and whose competitors pose unusual threats. In order to succeed in these niches, a firm often will require an unorthodox approach (Scott 1987). Companies with diversified markets will also be able to spread their business risks: they can afford to gamble with unconventional methods in at least some of their markets, since they have others to fall back on (Chandler 1962; Palmer, Jennings & Zhou 1993).

Hypothesis 9. Competitive nonconformity is more apt to erode the performance of firms operating in homogeneous than in diverse markets. (That is, market diversity will moderate the relationship between deviation and change in performance.)

Method

SAMPLE

The scope of our initial database and our final sample was determined by our notions of markets and competition. We view markets as social structures among specific cliques of firms whose repertoires are based in part on the mutual observation of concrete actions (see Burt 1987; Granovetter 1985; White 1981). We have argued that competitive repertoires are very much shaped by the regular and continual interaction among rivals and their clients. Thus our sample consisted of enterprises of comparable market scope that were direct competitors of one another over a significant interval.

Our initial database consisted of all 32 "major" and "national" U.S. domestic airlines, excluding all regional airlines. The airline industry was chosen because of its competitiveness and its rich diversity of competitive tactics (Chen, Smith & Grimm 1992). The industry also contains firms about whose decisions there is abundant public information and whose business is concentrated in a single industry.

Unfortunately, 14 of the 32 airlines were niche rather than truly major carriers, and considerable information was missing for all these firms. More important, while the 18 "major" airlines competed and interacted with one another across the same competitive domain and over a common interval, the 14 smaller and more focused carriers did not. The 18 majors during 1979 to 1986 viewed each other as principal competitors; but they were not much influenced by the 14 nonmajors that were of far narrower market scope and more tied to and influenced by local conditions (such distinct local markets alone might account for any deviation from industry norms). Moreover, the potential competitive repertoires of the smaller airlines are constrained simply by the very scope and scale of their operations. Our 18 majors collectively accounted for more than 84% of the annual revenue passenger miles flown in the U.S. from 1979 to 1986 (versus less than 8% for the 14 airlines we dropped).

The period we chose to study was the postderegulation (but premerger) era, a time during which airlines would have to discover the rules of the game in order to compete effectively (Levine 1987). Such an interval was expected to provide much variety in competitive deviation both between airlines and over time.

For practical purposes, it is impossible to examine every action taken at all levels inside an organization. We therefore assess competitive deviation only in implemented, public, market-oriented actions — in those significant concrete actions that are observable by customers, competitors, and other industry participants. Minute adjustments such as isolated price changes were too incremental and invisible to fall within the scope of this study.

This research selected all competitive actions reported between 1979 and 1986 in *Aviation Daily*. Methods of "structured content analysis" were used to identify and classify these moves (see Harrigan 1980; Jauch, Osborn & Martin 1980; Miller & Friesen 1984). *Aviation Daily* is widely known in the industry as the publication that provides by far the most comprehensive information on airline strategy (Chen & MacMillan 1992; Chen, Smith & Grimm 1992).

IDENTIFICATION OF ACTIONS

An extensive eight-year review of every issue of *Aviation Daily* was conducted to document 21 types of competitive moves in the following categories: changes in price, promotional activities, product line or service changes, distribution channel alterations, market expansions, intraindustry mergers and acquisitions, and strategic alliances. This focus was derived from the strategic content research of Hatten, Schendel & Cooper (1978), Khandwalla (1981), Porter (1980, 1985), and Scherer (1980). It incorporated all actions reported in *Aviation Daily* that airlines took in these categories. The types include all the important competitive moves identified by Levine (1987) in his comprehensive review of airline competition since deregulation. The only omission from his list was the use of computerized reservation systems. This action was unreliably reported in our data and relates mostly to internal operating practices that were beyond the scope of our analysis. The total sample consisted of 891 actions. Our efforts to establish the comprehensiveness and reliability of the information reported in *Aviation Daily* are described in Chen, Smith & Grimm (1992) and in Miller & Chen (1994).

OPERATIONALIZATION OF VARIABLES

Competitive Nonconformity

The measure of competitive nonconformity reflects a firm's deviation from the annual industry norm in its repertoire of actions. This index, computed for each of the $j = 1, \ldots, 18$ airlines, for each of the $t = 1, \ldots, 7$ years, is based on the number of each of the $i = 1, \ldots, 21$ types of actions that a firm makes compared to the sample average for that year. Some kinds of actions (e.g., alliances) are much less common than others (e.g., price cuts). Thus to avoid underweighting the former vis-à-vis the latter we computed standardized values ($M = 0$, $SD = 1$) for each type of decision across all firms. We did this separately for each year to allow for annual differences in industry strategies. Then we took the absolute value of the standard scores $|z^{t}_{i,j}|$ to represent deviations from that year's industry average for each type of decision. These absolute values were summed across all 21 types of actions to yield an unadjusted cumulative index of deviation from the industry norm (Cronbach's $\alpha = 0.82$). The natural log of this sum was taken to normalize the coefficient.

$$\textit{Unadjusted deviation index}\,(t) = \ln\left(\sum_{i} |z^{t}_{i,j}|\right)$$

This index is not purely a measure of deviation, for it tends to increase with the number of actions taken by a firm, thereby producing tautological relationships with size, diversity, and even age. It was necessary to remove this effect by eliminating that portion of the measure that reflects only the amount of activity. To do this, the unadjusted index of deviation was regressed against a total annual index of competitive activity that we calculated for each firm.[3] Our final

adjusted index of competitive deviation is composed of the residuals obtained from the above regression and reflects only nonconformity.

In principle, it would have been possible to use the unadjusted deviation index in our analyses and to control for the amount of activity by employing it as an independent variable. In fact, however, problems of multicollinearity resulted from the strong relationships between the activity index and the other independent variables of size, diversity, and age.[4]

Deviation in Tactical versus Strategic Actions

To establish the range of application of our findings we computed deviation indexes both as described above for all 21 types of actions and for a subset of "tactical" actions only. It could be argued that nontactical actions occur so rarely that whenever they take place they imply some deviation from the industry norm. Therefore we wished to determine whether our findings would be replicated after we deleted nontactical actions. We define tactical actions as those that involve no significant or long-term investments in fixed assets, people, or structure and that are in general quite reversible (Chen, Smith & Grimm 1992). The 21 generic types of actions were classified as tactical or nontactical by three raters working independently. There was total agreement among the raters in making the classification.[5] Only seven kinds of actions were deemed to be nontactical: mergers and acquisitions, hub creations, feeder and interindustry alliances, new services, frequent flyer programs, and new airplane purchases.

Performance

Performance was measured by operating revenue per available seat mile flown — R/ASM. This index has the advantage of reflecting not only the load factor of an airline, that is, the percentage of seats it fills, but also the revenue produced thereby. In addition, it avoids counting as good performance high load factors that come at the cost of inadequate revenues. Revenue per available seat mile is also very appropriate for our analyses as it is updated for most airline executives very frequently and thus can have a rapid impact on strategy. Measures such as return on equity or return on assets were avoided, because they are influenced by interest rates, debt-equity ratios, tax anomalies, depreciation policy, and other factors having little connection with the actions composing our deviation measure. Profitability and cost indexes of performance are also less relevant, since the present study looks only at external, market-oriented actions, not internal operating decisions.

Organizational Variables

Firm age was measured in years and size was simply the natural log of the number of full-time employees. Slack resources were assessed using Bourgeois's (1981) measure of annual general and administrative expenses as a percentage of annual operating expenses obtained from the annual publication *Air Carrier Financial Statistics.*

Environmental Variables

Market diversity was measured by two indexes, the first measuring customer diversity, the second, competitor diversity. The diversity of customers was reflected by the distribution of a carrier's business across the 37 largest U.S. airports; this was computed as the Gibbs-Martin (Gibbs & Martin 1962) index of heterogeneity:

$$\sum_{K=1-37}\left[\frac{A's\ passengers\ at\ airport\ k}{A's\ passengers\ across\ 37\ airports}\right]^2$$

This index is an inverse index of diversity; it will equal 1 if the airline serves only one airport and will approach 0 if its passengers are equally divided across the airports. To make it reflect diversity, the sign of this index is reversed when we report our findings.

The diversity of competitors was assessed as follows:

$$\sum_{K=1-37}\left[\frac{A's\ passengers\ at\ airport\ k}{A's\ passengers\ across\ 37\ airports}\right] * N\ of\ rivals\ at\ k$$

This index will be large to the extent that airline A's important markets have many competitors.

Information was obtained from the U.S. Department of Transportation's publication titled *Airport Activity Statistics of Certified Route Carriers*. Its data provide some indication of the variety of markets and passengers served and hence of the diversity of competitive conditions and customer demands that airlines must confront (Levine 1987).

Market growth was measured by the level of growth in total industry business volume, an indicator of the degree to which new markets or niches are opening up (Levine 1987). This was assessed by the annual change in total revenue passenger miles flown for the entire domestic airline passenger business.

We chose as our measure of time the number of years since deregulation in October 1978. Deregulation was an environmental jolt that severely disrupted the old methods of competition and threw the industry into competitive disarray and chaos. As time passed, the industry again began to settle down and become more competitively isomorphic (as our analyses will show).

ANALYSES

Since data were collected on 18 airlines over 8 years it was useful to correct for potential autocorrelation due to time and for heteroskedasticity caused by cross sections (Sayrs 1989). To do this we employed Kmenta's (1986) autoregressive-heteroskedastic model for pooled time series — cross-sectional data. The Kmenta model is

$$Y_{it} = b_1X_{it,1} + b_2X_{it,2} + \ldots. + b_kX_{it,k} + E_{it}$$

where i equals 1, 2, . . . , N, t equals 1, 2, . . . , T, k equals 1, 2, . . . , K. K equals the number of explanatory variables, N equals the number of cross-sectional units (18), and T equals the number of time periods (7 — one was lost due to

lagging). We applied the above model to data corrected for autocorrelation and heteroskedasticity. To correct for first-order autocorrelation, the Prais-Winsten transformation, which preserves the first observation of each cross section, was applied to each firm individually. Plots of residuals, rapidly declining correlograms, and nonsignificant Durbin *h* statistics revealed that all autocorrelation had been removed by the correction and that no higher-order autocorrelation was present in the data. In a second step, the data were corrected for heteroskedasticity by dividing dependent and independent variables by the firm-specific error variance obtained from the regressions on the autocorrelation-corrected data. Subsequent plots of residuals revealed an absence of heteroskedasticity. The twice-transformed data could now be pooled and analyzed using OLS regression (see also Judge et al. 1988, Section 11.5).

In examining the moderating effects of size and diversity on changes in performance (Table 4), the components of the interaction terms were standardized before multiplication to remove any multicollinearity with the main effects (Smith & Sasaki 1979; Southwood 1978). Separate models were run for each interaction analysis to avoid multicollinearity between the interaction terms. For each model, the significance levels reported are those computed for the additional variance explained by the interactions after all noninteraction variables have been introduced into the model.

[a] For the smallest sample size, all coefficients greater than .19 and .24 are significant at beyond the 0.05 and 0.01 levels, respectively.

Findings

Descriptive statistics and correlations are presented in Table 2, and the results of the multiple regression analyses are given in Tables 3 and 4.

Table 3 indicates that hypothesis 1 received partial support while hypothesis 2 was well supported: the market context did influence the level of nonconformity. Operating in markets with a diversity of customers was associated with overall nonconformity, but not with tactical nonconformity. By contrast, having a diversity of competitors contributed to tactical but not to overall nonconformity. Perhaps a diversity of customers and markets generates ideas and demands for creative combinations of new services, hubs, alliances, client programs, and equipment alterations — the kinds of actions that we deemed to be nontactical. But day-to-day competition with a diversity of rivals appears to elicit noncon-

formity in the profiles of more routine actions such as price increases and decreases, route entries and exits, and small promotions — actions that are the stuff of everyday rivalry.

As predicted by hypothesis 2, nonconformity declined with the time since deregulation. After the shock and some initial groping and experimentation, companies began to resemble each other more and more in the way they competed (see DiMaggio & Powell 1983, 1988).

There was mixed support for the firm-level variables of our model. We found modest relationships of size and slack resources to total nonconformity but not to tactical nonconformity. Hence hypothesis 3 was not well substantiated, perhaps because we focused only on the largest airlines. There was support, though, for hypothesis 4: older firms were indeed more reluctant to deviate from industry norms.

Hypotheses 5 and 6 were supported as well. Both a climate of market growth and poor performance seemed to provoke competitive nonconformity for the total set of actions and for the tactical set of actions. The economic component of our model was strongly borne out.

The results in Table 4 confirm that competitive nonconformity was indeed associated with declines in performance (hypothesis 7). The central tendencies in an industry tend to be somewhat functional, and deviations from them may

be hazardous. Although some deviations no doubt pay off, it seems that in our sample, the risks and dangers outweigh the rewards. And this is consistent with the views of many institutionalists (Meyer & Rowan 1977; Zucker 1987).

The results in Table 4, however, suggest caution in evaluating hypotheses 8 and 9. Size and customer diversity were important moderators of the relationship between nonconformity and change in performance. Specifically, the relationship between nonconformity and performance became positive for the largest firms and for those with the most diverse markets. In order to assess the interaction effects more precisely, we calculated saddle points for the regression equations using the method of partial derivatives outlined by Gupta & Govindarajan (1993) and Harrison & Mitchell (1995). Only the largest 15% or so of our firms show a positive relationship between nonconformity and performance, while 85% show a negative relationship. The results are essentially the same for tactical nonconformity, with the percentages being 86% and 14% respectively. For customer diversity, only those 21% of firms with the greatest

diversity exhibited a positive relationship between nonconformity and performance; the rest had a negative relationship. For tactical nonconformity, the corresponding percentage is also 14%. The interaction effect for competitor diversity, however, was almost nonsignificant, perhaps because such diversity is less indicative of a firm's need to cater to different market demands. To recap, nonconformity is useful only for the top quintile or so of airlines with the largest size and the greatest customer diversity.

It was encouraging that most of the hypotheses were supported and that the results converged both for the whole set of decisions and for the tactical decisions alone. It is also notable that findings based on a seven-year rather than an annual standard for assessing nonconformity (available from the first author) replicated most of the results of the present study.

Discussion and Conclusion

SOCIOLOGICAL APPROACHES TO COMPETITIVE NONCONFORMITY

Competitive nonconformity is sometimes attributed to the genius or aberrancy of top managers or the corporate cultures these people create (Miller 1990). And when considered by economists, nonconformity is viewed in the context of distinctive competencies and their economic rents (Porter 1980, 1985; Prahalad & Hamel 1990). No doubt these are valuable approaches. One of the most interesting findings to emerge from this study, however, is that nonconformity also can be studied froma socIt is no contradiction to the value of these findings to note that markets can be viewed as social structures that over time exert a socializing influence on their members (Granovetter 1985; White 1981). As Wellman and Berkowitz (1988) state, "markets are social structures and not the spontaneous products of aggregated dyadic exchanges. . . . The ways in which actors observe and respond to others — the essence of a market — can be determined in the same fashion as any other socially structured activity" (222). Indeed, we found that the nonconformity of market participants arose in part from their social context and in part from their relationships to that context. Specifically, the extensiveness and continuity of a firm's interactions with its market contributed significantly to its level of nonconformity.

But we do not embrace a deterministic or "oversocialized" view of markets. A firm's temporal and extensive degree of embeddedness within the existing structure of social relations is of crucial importance, and this varies both among contexts and among firms within a context. Hence we must reject both the determinism of universal norms and the atomistic rationality of economists. Perhaps Granovetter (1985) says it best: "Actors do not behave or decide as atoms outside a social context, nor do they adhere slavishly to a script written for them by the particular intersection of social categories that they happen to occupy. Their attempts at purposive action are instead embedded in concrete, ongoing systems of social relations" (487). Indeed, concrete "social relations, rather than institutional arrangements" are most essential, and these "networks of social relations penetrate irregularly and in differing degrees" even in the same market (Gronovetter 1985:491).

The current findings, tentative though they may be, provide early empirical confirmation of the usefulness of a sociological approach to markets (Granovetter 1985; White 1981, 1988; Winship & Rosen 1988). The sociological approach has, it seems, much to say about how competitive repertoires are shaped, not just in regulated contexts, but in highly competitive markets. Our research also shows how nonconformity can be operationalized objectively and as a continuous variable. This may enable subsequent researchers to avoid "all or nothing," and hence oversocialized and undersocialized, market perspectives.

Our enthusiasm for the sociological view notwithstanding, we should not forget that nonconformity is influenced powerfully by economic stimuli as well — most importantly by the rate of market growth and poor financial returns. Sociological perspectives complement but do not replace economic approaches to the study of competition (Powell 1991; Winship & Rosen 1988; Zald 1978). Although the two approaches stress different sources of nonconformity, each is

important, and together they provide much incentive to broaden the conceptual rationales used to study markets.

Neither must we overstate the separation between economic and sociological influences. As one perceptive reviewer has suggested, the economic and sociological perspectives of markets vary in the observables that are taken to determine behavior. Economists concentrate more heavily on prices and costs, whereas sociologists, who also recognize the importance of these factors, are interested as well in the social contexts that influence which observables managers see and react to. This set of stimuli can be quite large. And as we indicated in the discussions preceding hypotheses 5 and 6, economic incentives may be influenced by the social context. Similarly, some types of social interaction might evoke economic reasoning. It may be as Braudel (1982) claims, that "all forms of exchange are both economic and social" (227).

NONCONFORMITY AND PERFORMANCE

Many institutionalists see organizations as adopting various stratagems, policies, and administrative practices not so much to improve their efficiency or reliability but rather to secure the legitimacy that will gain access to resources and status (Meyer & Rowan 1977). According to DiMaggio & Powell (1983) a primary mechanism that organizations use to achieve legitimacy is conformity to industry norms. Deviant organizations that use unorthodox techniques to compete may be punished (Chen & Hambrick 1995). This, to some degree, is borne out by our results — but mostly for smaller firms operating in homogeneous markets. One reason for the superior results of companies pursuing "isomorphic" or conventional repertoires may be that they are more acceptable to competitors, customers, and even suppliers of capital. It may also be that deviant repertoires are risky in and of themselves — they ignore the wisdom that is often reflected in industry consensus.

The arguments of the institutionalists do not appear to apply, however, to large and diverse organizations that can actually benefit from their nonconformity. This exception is important, for it is precisely in industries with few large firms where institutional theory should receive the greatest support. Mezias (1990) and Scott (1987) seem to be right, then, in calling for the qualification and contextualization of institutional hypotheses.

These results have potential implications for industries such as airlines that have been undergoing a rash of mergers. Initially, the creation of organizations that are free of tradition may give rise to unconventional strategies. As we have seen, new companies and industry upheavals make for a wider range of idiosyncratic strategies. Ultimately, however, mergers cause industry concentration, and this may reduce diversity and thus enhance the conformity of strategies. In this regard, the U.S. automobile industry may be a suitable target for study.

This research also has implications for scholars of strategic management. Barney (1991), Porter (1980, 1985), Prahalad and Hamel (1990), and others have argued for the benefits of developing distinctive competencies. To the extent that these competencies demand unique competitive profiles, however, there may be some constraints on this pursuit, especially for small firms operating in

homogeneous markets. For them, the development of distinctive competencies should probably not come at the expense of abandoning important industry conventions. In these instances, competitive conformity may have more advantages than deviation in procuring resources and legitimacy, meeting the expectations of customers, regulators, and other stakeholders, and avoiding hostile retaliation.

Clearly, this research raises more questions than it answers. The notion of competitive nonconformity is new and could benefit from more precise articulation and alternative definition. Another limitation of this study is that we could not discover the precise motivations for nonconformity, nor could we assess the performance implications of the individual components of nonconformity. Moreover, internal policies and resources have much to do with competitive deviation and originality (Barney 1991), yet these could not be examined in this research. Company structures, cultures, and top management teams also will no doubt influence nonconformity, but these were not treated here. (For one investigation, see Keck & Tushman 1993.) And there are other institutional forces such as legal, professional, and competitive contexts that might have a bearing on competitive conformity (DiMaggio & Powell 1991). All these gaps in this study suggest avenues of further research as does the challenge of replicating our findings in other industries.

Notes

1. We would expect that periods of precipitous decline or collapse in an industry would also trigger deviations from the norm as companies seek new ways to survive. But this assymetrical relation could not be tested, since our industry never did experience such an interval (see also Lieberson 1985:124).

2. Some might argue that poor performance erodes organizational resources, and that this increases the pressure to conform. This usually will be true only of long-term performance deterioration. Indeed, resource scarcity is the concern of hypothesis 6.

3. The activity index was composed of the same elements as the index of deviation but without taking their absolute value:

$$\textit{Activity index}(t) = \ln\left(\sum_{I} z_{i,j}^{t}\right)$$

4. We also assessed the possibility of deriving homogeneous groups or clusters of airlines based on repertoire similarity and then using distinct standards for assessing nonconformity within each group. Unfortunately, no clear groups emerged from various clustering attempts (single and average linkage algorithms using Euclidean distance measures and Ward's criterion) or from *Q*-factor analysis.

Clustering was performed using the standardized scores for the 21 types of actions. We found that airlines moved between clusters from year to year and that clusters seemed to vary only slightly and in no thematic way — the meanings of most clusters were obscure. Moreover, one cluster accounted for most observations. The small "fringe" clusters that emerged contained mostly regional carriers that were ultimately deleted from the sample in this study. When we used a holdout sample to establish the stability of the clusters, the original clusters were not replicated. Matters did not improve after we had removed the "outlier" clusters, which merely produced a few new outliers. (It seemed inadvisable to use the small clusters as a basis for calculating deviations, as these were at odds with industry norms, and their members merely conformed to the behavior of a similarly unorthodox partner.)

We also found it impractical to derive clusters based on geography or on the frequency of competitive interaction among the airlines. Virtually all the larger airlines interacted with each other in a great many of their routes. A few of the smaller airlines did emerge as being outside

the pack, but these represented fewer than 6% of our observations. Given these results, it seemed reasonable to use industry central tendencies as the bases for assessing nonconformity.

5. To confirm the validity of the classification, a questionnaire was distributed to six management professors with expertise in both competitive strategy and the airline industry. The respondents were asked to categorize various types of actions as strategic or as tactical using the above definitions. Interrater reliability was 1.0 for 20 items, and 0.83 for one item. There was only a single misclassification in the entire exercise.

Labor Market Structures in Japan: An Analysis of Organizational and Occupational Mobility Patterns*

MARIAH MANTSUN CHENG, *University of North Carolina at Chapel Hill*
ARNE L. KALLEBERG, *University of North Carolina at Chapel Hill*

Abstract

In this article, we examine patterns of occupational and organizational mobility among Japanese men. Contrary to conventional wisdom, we find that Japanese men often change employers as well as occupations during their careers. Using a conceptualization of internal labor markets that distinguishes between firm internal labor markets (FILMs) and occupational internal labor markets (OILMs), we tested various hypotheses about the determinants of four patterns of job shifts formed by cross-classifying firm and occupational mobility. Our results suggest that men in larger organizations (who we assumed are more apt to be in FILMs) are more likely than those in smaller firms to experience within-firm mobility, while men in tiny firms make more across-firm shifts. In addition, men in professional and technical occupations (who we assume are more likely to be in OILMs) experience more within-occupation mobility.

Japanese workers are commonly perceived as having relatively stable relationships with their employers. Publicity about the cultural uniqueness of permanent employment and managerial styles in Japan (e.g., Abegglen 1958; Vogel 1979) has helped to foster the belief that Japanese employees work for the same employer almost all their lives and enjoy numerous internal promotion opportunities. Academic discussions also regard the lifelong employment and seniority wage system as two of the "three pillars" of Japanese industrial relations (the third being enterprise unionism) that have facilitated the nation's

* *Revision of a paper presented at the 1994 annual meeting of the American Sociological Association in Los Angeles. We are grateful to Aage B. Sørensen, Robert P. Althauser, Michael Hout, David Guilkey, Kazuo Yamaguchi, Rachel Rosenfeld, Arthur Sakamoto, Guang Guo, Lynn Igoe, and the anonymous reviewers for their helpful comments at various points as we developed this article. Thanks are also due to the Carolina Population Center, University of North Carolina at Chapel Hill, because this research was made possible by its support through a postdoctoral fellowship funded by the NICHD National Research Service Award (5-T32-HD07168-16). immense economic growth since World War II (Odaka 1986). It is widely believed that Japan's path to modernization not only led to industrial excellence, but also provided its workforce with employment security and seniority-based opportunities for advancement.

However, a growing body of evidence suggests that this formulaic presentation of Japanese employment relations is misleading (Plath 1983; Shirai 1983). Although job mobility is lower in Japan than in the U.S. (Lincoln & Kalleberg 1990; Mincer & Higuchi 1988; Tachibanaki 1984), studies have found a considerable amount of career mobility among Japanese men. Levine (1983) calculated that, on average, a Japanese man changes firms at least three times during his work life, while Hashimoto and Raisian (1985) found that a Japanese man typically changes jobs five times before he retires at age 65. Thus, the notion of "lifetime" employment undoubtedly overstates the stability of the Japanese employment system and underestimates actual job mobility.

Dwelling on the cultural uniqueness of Japan's system overlooks variations in employment experiences among different sociodemographic groups in Japan and neglects to consider that many "unique" Japanese phenomena can be accounted for by universal processes common to industrial societies (Aoki 1984; Cole 1979; Levine 1983; Taira 1970). Many scholars point out that lifetime employment applies only to regular primarily male employees in large, private firms or government agencies (Dore 1973; Marsh & Mannari 1971; Taira 1962).[1] Young women, though sometimes hired as regular employees in large firms, are expected to leave after marriage or first childbirth; older women who rejoin the labor force commonly do so as temporary workers (Brinton, Ngo & Shibuya 1991; Rohlen 1979). Consequently, women are customarily excluded from the lifetime employment system, as are men in small companies, and temporary and "outside workers" in large firms (Chalmers 1989). Some researchers even suggest that employees under a lifetime system constitute no more than a fifth of Japan's work force (Cole 1979; Taira 1962).

Unfortunately, despite widespread interest in Japan's employment system, there is little empirical evidence on patterns of employer changes. We provide evidence on one important aspect of this system: patterns of occupational and organizational mobility among Japanese men. We argue that the directions and kinds of job shifts reveal much about types of firm and occupational labor market structures. We first describe the structure of labor markets in Japan. We then generate eight hypotheses about the correlates of inter- and intra-occupational and firm mobility patterns in Japan, and test them by multinomial logistic regression analyses of retrospective mobility data from a Japanese national survey.

Structure of the Japanese Labor Market

INDUSTRIAL DUALISM AND DUAL LABOR MARKETS

Three related notions are frequently invoked in discussions of Japanese labor market structures: industrial dualism, dual labor markets, and firm internal labor markets (FILMs). Japan is described as having a dual economy polarized by firm size, internal organization, and wage structure. One sector (the "core")

consisting of large-scale, capital-intensive organizations and high-wage systems, coexists with a second sector (the "periphery") characterized by many small-to-medium scale, labor-intensive, and low-wage firms (Broadbridge 1966; Minami 1986; Nakamura 1981).[2] While a dualistic economic structure is certainly not unique to Japan (e.g., see Berger & Piore 1980), Japanese dualism has been argued to be distinctive in that, as compared to other industrial countries, the wage differential and mobility gap between the two sectors are much wider (Ernst 1986), the interlocking between large and small firms is tighter, and the subcontracting and subsubcontracting hierarchy more far-reaching (Tatsumi 1971).[3]

Corresponding to this dual industry structure, the Japanese labor market is said to be divided into two segments — one for jobs in large, core firms, the other for jobs in the small or medium, peripheral firms (Broadbridge 1966; Chalmers 1989; Ernst 1986). The concept of a dual labor market consisting of "primary" versus "secondary" segments describes the differential employment conditions that workers face in large versus small firms. Male, regular employees in large firms are primary workers employed in the core firm sector who occupy good jobs and enjoy high wages, good promotion prospects, and permanent, stable employment; by contrast, secondary workers, such as temporary employees, part-time workers, older women, or men coming from second-rate schools, are employed in bad jobs in small firms in the periphery, and receive low wages, limited chances of promotion, and minimal job security.

FIRM INTERNAL LABOR MARKETS

Firm internal labor markets (FILMs) are a useful concept for describing why members of core firms and primary labor markets can experience upward mobility and career advancement. FILMs are groups of jobs within organizations that are characterized by: "(1) a job ladder, with (2) entry only at the bottom, and (3) movement up this ladder, which is associated with a progressive development of knowledge or skill" (Althauser & Kalleberg 1981:130). A firm with a structured FILM has a well-developed set of administrative rules and customs that govern promotions, wages, and benefits (Doeringer & Piore 1971). FILMs ensure a stable employment relationship that facilitates the implementation of effective on-the-job training for firm-specific skills necessary for advanced technological production. By contrast, firms that lack FILMs provide little on-the-job training, low wages and benefits, unstable work, and little or no chance for career advancement. Most jobs within unstructured labor markets require few firm-specific skills and can be performed by any worker who holds some general skills.

Some researchers argue that the permanent employment and seniority-based reward systems in Japan should not be seen simply as manifestations of industrial dualism or employer paternalism, but as elements of FILMs (Cole 1972, 1973; Koike 1983). The permanent employment policy was adopted in the 1920s by large firms as a pragmatic means to stabilize their regular work force (Minami 1986) by reducing employee turnover, and lowering the cost of retraining skilled and technical staff (Cole 1979). While the seniority-based reward system is a mechanism to defer wage payment by underpaying younger

workers, it also facilitates on-the-job-training and job rotation by detaching remunerative rewards from one's immediate task. The historical account for the emergence of FILMs in Japan also echoes the significance of firm-specific skill training as a crucial determining factor.

The institutionalization of FILMs coincided with the urgent needs for firm-specific skill training in large corporations during the 1920s. Spurred by the World War I (1914-18) economic boom, big enterprises flourished in heavy, chemical, and machinery manufacturing industries. To remain competitive, they imported new, foreign technologies from many countries (Helvoort 1979). Machine tools and equipment adapted to local factory conditions varied greatly in design, and so were the particular skills required for their operations. With little public vocational training, and the pressing needs for ready-to-use, firm-specific skills, large companies had to establish internal programs for technical training (Levine & Kawada 1980). To arrange for firm-specific skill training and to secure returns from investments in human capital, these firms progressively tightened their control over recruitment, job allocation, and rewards of skilled workers. The traditional master-apprentice relations were co-opted and brought under their bureaucratic managerial control. The once highly mobile master craftsmen, who governed the supply, training, and compensations of skilled labor, received permanent tenure and supervisor titles in the firms, and their apprentices were turned into regular wage employees (Levine 1965). They were then responsible for training new graduates hired directly from schools. Permanent employment and seniority-based reward systems were applied to skilled workers to reduce their mobility across firms and to facilitate training within the firm.

How do Japanese FILMs differ from those, say, in the U.S.? Some claim that a permanent employment guarantee carries more normative weight in Japan. Regular (male) employees expect lifelong employment, particularly from large employers who are presumed to be capable of fulfilling that obligation. Consistent with this claim, we see that large Japanese firms are under considerable social pressure not to lay off employees except as a last resort during recession[4] (Ernst 1986; Rohlen 1979). Compared to the U.S., wage promotion in Japanese FILMs is based on a ranking hierarchy that is more a function of seniority than job content (Sakamoto & Chen 1992). Accordingly, we see that job descriptions and classification are less detailed in Japan (Cole 1979) and job rotation is less rigid (Hashimoto 1990).

OCCUPATIONAL DIMENSION OF LABOR MARKETS

Internal labor markets are not only structured by firms, but also by occupations. (See Althauser & Kalleberg's 1981 discussion of OILMs, Doeringer & Piore's 1971 discussion of craft submarkets and mobility clusters within firms, and Osterman's 1984 distinctions among the "industrial," "craft," and "secondary" subsystems within firms.) "Occupation" refers to technical work activities that are transferable among employers and to skills that are transportable from firm to firm. Hence, work activities that are structured on the occupational principle tend to be bought and sold in labor markets that are external to a particular firm. Both firm internal labor markets (FILMs) and occupational internal labor

markets (OILMs) have the common structural features of an internal labor market: people who hold jobs in internal labor markets can move upwards on job ladders and acquire progressively greater work skills. A difference between them is that job movements in FILMs are usually within a single firm, while those in OILMs are within a single occupation but may often span firms. Another basic difference between FILMs and OILMs is who controls the employment relationship: while FILMs are basically governed by the employers, OILMs are greatly influenced by the incumbents of specific occupations. People with occupational skills that require special talents or long periods of learning often form associations (e.g., professional association, craft union) to protect their shared interests and influence the labor market processes. Some occupational groups directly set a monopolistic price for their service, others affect the market by controlling the supply of their skills. They govern the qualification procedures, specify standards and ranks, and thereby, occupational internal labor markets are developed.

FILMs and OILMs may overlap, since, in some situations, employment relations may involve occupations and firms simultaneously (Bridges & Villemez 1991; DiPrete & McManus 1993). For instance, firms might compete for the loyalty of someone who is in an OILM (such as a lawyer or other professional) by offering opportunities for promotion and advancement within the firm. If someone is concurrently in a FILM and an OILM, however, it is the occupation, rather than the firm, that circumscribes his labor market since he can change firms while continuing to move up an occupationally defined job ladder. By contrast, if someone who is only in a FILM leaves the firm, this in effect means he must enter the new firm's FILM at the bottom, as most ports of entry are at the bottom of job ladders. For this reason, whether or not one is in an OILM will affect his propensity of making moves across firms or occupations.

One feature claimed to be uniquely Japanese is workers' identification with firms rather than occupations. Occupation has not been given much attention as a factor in determining workers' careers and mobility chances, and it is indeed often ignored in analyses of Japanese labor market structures.[5] Low occupation consciousness among the Japanese has been explained by the so-called "groupism" orientation. In the past, Japanese group consciousness was represented by the concept of *ie* — the traditional household institution. In modern days, the *ie* notion has been carried over to the firm — which is conceived as a united, family-like group (Kaneko 1980). As in a family, employees are permanent members of the firm. The relationship between employee and employer is diffused and lifelong. Total commitment and obligation on both sides is expected, and remuneration is awarded according to an employee's length of membership (seniority) and loyalty. Association within the group is exclusive, and identification with outsiders is greatly discouraged. Japanese tend to form groups according to their common *frame* (e.g., a firm), not their *attributes* (e.g., occupational characteristic) (Nakane 1970). The vertical relation (e.g., super- vs. subordinate) is the primary acting principle for groupings and identification, and thereby undercuts the horizontal relation that binds people of similar attributes together (e.g., class formation or occupational connection).[6]

The occupational principle has less importance as a work-structuring form in Japan, especially in its large-firm sector, as is indicated by the low occupational consciousness and vague job classification schemes. Historically, the craft guild tradition was weak as the country was suddenly awakened to industrialization by the jolt of Western intrusion. When large industrial firms began to mushroom in the late 1910s and 1920s, many craftsmen were co-opted into their bureaucratic management. Traditional skilled labor was eventually replaced by internally trained youngsters recruited from schools, and the master-apprentice relations that organized skilled workers along craft lines within large firms were dissolved. Other craftsmen survived by establishing their own businesses or working for small firms in the competitive sector (Jacoby 1979). Craft unions — occupational associations of allied workers — flourished in the upsurge of labor movements during the 1920s and 1930s. However, they were later driven out by the *Sampo* (the Industrial Patriotic Labor Association) movement (1939-45), a patriotic movement orchestrated by the military government to elicit workers' cooperation with management and to support the war through production (Taira 1970). Radical labor movements immediately after the war were again suppressed. Superseding trade unions were enterprise unions, which built on the structure of *Sampo*, uniting all *regular* employees within the *same* company regardless of their occupations (Helvoort 1979). Excluding other temporary employees, workers organized themselves on an enterprise basis, with permanent employment and seniority wage as their main objectives. Unlike before, union memberships were no longer concentrated among small-firm workers, but among large-firm workers. This principle of unionism — an enterprise-based union that unifies labor and management interests by tying employees' benefits to the ultimate survival (thus profit) of their own company — inevitably perpetuates the dual labor market segmentation and limits workers from joining with their counterparts (by occupation or class) across firms.

Despite all this, however, evidence still points to the importance of occupational differences for mobility in Japan. Using the 1975 Social Stratification and Mobility Survey, Cheng (1991) found that the odds of Japanese men's remaining with their first employer depend on firm size *and* occupation; and given that employer changes occur, then mobility distances among employees reflect the socioeconomic status of their occupational types, with rank order strikingly similar to that in the U.S. (Cheng 1995). Moreover, though to a different degree, large and small firms in Japan rely on the external labor market for their recruitment. Regardless of firm size, the types of experienced workers most sought after are production engineers, computer specialists, personnel and general managers, managerial planners and researchers, finance specialists, and sales promoters (Beck & Beck 1994). Midcareer recruitment targets professionals and managerial workers with high-level technical or special skills. While the trend for increased mobility among all workers is apparent,[7] the rise among professionals is remarkable. In the 1980s, across-firm mobility among male engineers, professionals, managers, and official employees increased by more than 10% annually, exceeding the traditional highest mobility group of skilled workers in the production, transportation, and communication industry (Beck & Beck 1994). As indicated in various case studies, Japanese employees, like many of their counterparts in the U.S., are involved assiduously

in attempts to shape their own careers (see Plath 1983). Professionals, because of the empowerment of their specialized knowledge, demonstrate that under some circumstances, the occupational principle of work control can take over from the administrative principle, even in Japan's large-firm sector.

Hypotheses

The distinction between firm and occupational internal labor markets is useful for understanding the dynamics of job mobility and careers. This conceptualization focuses our attention on "episodes" of labor force experiences as a worker progresses through a career, instead of assuming that individuals are static and always belong to a particular labor market. We use the concepts of FILM and OILM to examine the structural elements of Japanese employment practices and how they might be similar to work arrangements in other industrial social settings. We assume that the observed patterns of job mobility are manifestations of the latent labor market structures (DiPrete & McManus 1993) and postulate four specific types of mobility patterns that are generated by the underlying firm and occupational labor market structures (see also Kalleberg & Hudis 1979). Firm size and occupational types are the key variables that designate the locales of these internal labor markets, whereas the labor market structures are empirically manifested by the tendency of their incumbents to make these various types of job shifts. By specifying hypotheses about the observed mobility patterns associated with the concrete firm size and occupational types, we investigate the structure of the Japanese labor market from the firm and occupation internal labor market perspectives. Table 1 summarizes our hypotheses.

FIRM SIZE

Larger firms are more likely than smaller firms to establish and maintain FILMs because larger firms have more stable sales, higher profits, higher productivity, and more technologically sophisticated production. Large firms are thus better able to provide high employment tenure, high wages and benefits, and internal promotion opportunities. Recruitment preferences go to new graduates or young workers, training is mainly on-the-job, and higher positions are filled from within based primarily on seniority. By contrast, small firms are less likely to develop FILMs because of their unstable sales, less capital-intensive production, limited resources, and higher bankruptcy rates. Consequently, small firms are less able to guarantee stable and lifelong employment or to provide many internal promotion opportunities. With less technologically sophisticated production, firm-specific on-the-job training also becomes less essential. As workers can be more readily substituted, a stable employment relationship is not of great concern to the employer, at least not when the labor supply is abundant. These observations suggest that,

Hypothesis 1: Men in larger firms are more likely than those in tiny firms to be in FILMs. Thus, firm size should be positively related to intrafirm mobility and negatively related to interfirm mobility.

TABLE 1: Hypotheses

	Within-Firm Within-Occ. (FILM)	Within-Firm Across-Occ. (FILM)	Across-Firm Within-Occ. (OILM)	Across-Firm Across-Occ. (SLAM)
Firm size	+	+	-	-
Occupations (vs. unskilled workers)				
Professional	+	-	+	-
Managers	+	-	+	-
Clerks	+	+	?	-
Skilled workers	+	-	+	-
Semiskilled workers	?	+	+	-
Unskilled workers	lowest	lowest	lowest	highest

Hypothesis 2: Men in tiny firms are more likely to be in unstructured, secondary labor markets (SLAMs) than men in large firms. Consequently, men employed in tiny firms are more likely to change occupations and firms simultaneously than those in large firms.

PROFESSIONAL AND TECHNICAL OCCUPATIONS

Professional and technical occupations are exemplars of OILMs, since they require high levels of technical skills and professional training, much of which has to be acquired from outside the firm. Firms most often recruit for these occupations from the external labor market, since internal transfers face technical entry barriers. Moreover, these occupations' job skills are relatively highly "portable" and transferable to other firms. Therefore, professional and technical workers tend to remain in the same occupation when they change firms. At the same time, many incumbents of these OILMs are in FILMs as well, particularly in Japan. This suggests our third hypothesis:

Hypothesis 3: Professional and technical workers are more likely to be in OILMs. However, in some situations, these OILMs might overlap with FILMs. Thus, we expect them to be more likely to have across-firm, within-occupation and within-firm, within-occupation transitions than members of occupations who are not in OILMs, such as unskilled workers.

MANAGERIAL AND ADMINISTRATIVE OCCUPATIONS

Members of these occupations tend to have skills that are more firm-specific (idiosyncratic knowledge of the given firm) than those in professional and technical occupations. In addition, promotion tends more often to be from within the firm: probably from lower-level clerical positions (see Osterman's 1984 findings). Promotions are also more likely to be upwards along authority hierarchies, rather than to involve changes in the nature of one's work. Members of these occupations are more likely to be in FILMs, but changing occupations is less likely. This suggests the next hypothesis:

Hypothesis 4: Managerial and administrative employees are more likely to be in FILMs. Some, especially those at higher levels, may also be in OILMs, and be sought after by other firms. Therefore, overall we expect managers and administrators to experience more within-firm, within-occupation transitions, and to some extent, also within-occupation across-firm shifts, than unskilled workers.

CLERICAL WORKERS

Members of these occupations should have general, transferable skills, and low levels of technical skills. However, Japanese men classified as clerks are likely to perform lower-level managerial work, and so many are at the lowest rung of a job ladder that leads to management. Hence, we expect that at least a portion of male clerks are actually in FILMs — with relatively high probability of within-firm transitions, mostly across occupations — and will later on move into managerial jobs. Therefore, we hypothesize that:

Hypothesis 5: Male clerks tend to be in FILMs. Thus, they have higher probability of within-firm, across-occupation transitions than men in unskilled occupations.

SKILLED WORKERS

These occupations have technical skills that are likely to be transferable from one firm to another. In this sense, they comprise OILMs — much like professional and technical workers. We suggest that,

Hypothesis 6: Skilled occupations are likely to be in OILMs. Therefore, skilled workers — more than unskilled — tend to experience across-firm, within-occupation, and to a certain extent, within-firm, within-occupation transitions also.

SEMISKILLED WORKERS

Members of these occupations are somewhat more likely to be in OILMs than unskilled workers. However, their extent of within-firm or within-occupation mobility should be much less than that of professional technical or skilled workers. Hence, we expect that:

Hypothesis 7: Semi-skilled workers are less likely to have across-firm, across-occupation shifts, but higher likelihood of experiencing across-firm, within-occupation transitions than unskilled workers. However, compared with skilled workers or professionals, they have lower probability of within-firm, within-occupation shifts.

UNSKILLED WORKERS

Since these workers are unlikely to be in either kind of ILM and to have few general or firm-specific skills, we hypothesize that they are likely to be in secondary labor markets (SLAMs):

Hypothesis 8: Unskilled workers are less likely to have within-firm shifts, but higher risks of across-firm and across-occupation shifts.

Data and Methods

THE 1975 JAPANESE SOCIAL STRATIFICATION AND MOBILITY SURVEY (SSM)

The work history data reported in the 1975 SSM survey (Tominaga 1975) were used to test these hypotheses about Japan's labor market structures and mobility patterns. Although the data set is nearly two decades old, it is the latest SSM survey available to non-Japanese scholars.[8] Moreover, since much of the popular understandings of the Japanese employment system focused on the 1960s and 1970s, these data may provide a better test of those hypotheses than more recent ones. The 1975 SSM was a representative national survey for a random sample of men aged 20 to 69. It collected complete work histories and information on many job characteristics for 2,724 cases, of which 2,639 had some work history. Even though data were restricted to men, which limits our assessment of gender differences in mobility patterns, since most of the discussions regarding permanent employment and internal labor markets have focused on men, they are useful for assessing hypotheses associated with these employment relations.

In the survey, 27% of the respondents[9] were still in their first job, and 39% were still working for their first employer[10] when interviewed. The numbers of work history spells reported by each respondent ranges from 1 to 15, and 85% of the respondents reported four or fewer work history spells. About 17% of the sample experienced some kind of interruption in their career, such as unemployment, military service, or school. When job spells are distinguished from nonjob spells,[11] we find that the mean number of jobs ever held by all respondents is 2.6. The distribution of actual number of jobs reported[12] shows that 27% of the respondents have had one job, 30% have had two, 20% have had three, and 11% have had four.

Our analyses are restricted to employees' labor force experiences in the nonagricultural sector, since the farm sector and self- or family-employment are less relevant to the concept of firm and occupation labor markets. From the work histories of the 2,639 cases, we found that 2,169 have been in the nonagricultural employee sector. Although some of them were in the agricultural sector, being self- or family-employed at one time or another, we retained their nonagricultural, employee job histories for analysis.[13] Among the 2,169 cases, a total of 3,017 actual job shifts (transition from job to job) are reported during their stay in the nonagricultural employee sector.

MULTINOMIAL LOGISTIC REGRESSION MODELS

We infer the operation of particular labor market mechanisms from an examination of patterns of actual job movements. We postulate four specific types of mobility patterns as generated by the underlying firm and occupational labor market structures. Workers who change jobs could experience one of four mutually exclusive types of transitions: (1) within-firm, within-occupation, (2) within-firm, across-occupation, (3) across-firm, within-occupation, and (4) across-firm, across-occupation.[14] Hence, our dependent variable is an unordered, polychotomous response variable that indicates the occurrence of a *particular type* of job change. We use multinomial logistic regression techniques[15]

to model the relative odds of a specific type of shift as compared to another type.

To specify the model, let m be the total number of possible outcomes in the discrete-categorical response variable; $j = 1, \ldots, m-1$, indexing the occurrence of a particular type of job shift (e.g., $j = 1$ means a within-firm, within-occupation job shift; $j = 2$ means a within-firm, across-occupation job shift, and so on); and m be the base category for comparison (say, an across-firm, across-occupation job shift). Let P_j be the probability of a specific type of job shift. It can be expressed as a function of some explanatory variables X_i, with β'_j as the effect estimates:

$$P_j = \frac{e^{\beta'_j X_i}}{1 + \sum_{j=1}^{m-1} e^{\beta'_j X_i}}$$

and the base category:

$$P_m = \frac{1}{1 + \sum_{j=1}^{m-1} e^{\beta'_j X_i}}$$

Hence, the relative odds of a specific job shift type (versus the base type) is:

$$\frac{P_j}{P_m} = e^{\beta'_j X_i}$$

In its logit form:

$$\ln\left(\frac{P_j}{P_m}\right) = \beta'_j X_i$$

The β'_j estimates can be interpreted as the effects of the explanatory variables on the log odds of having a particular type of job transition relative to the base type.

Variables

MEASURING FILM AND OILM STRUCTURES

Firm size and occupational types are the variables that designate the locales of these firm and occupational labor markets. We assume that FILMs are more prevalent in larger firms, and that OILMs are more likely to be in professional/technical occupations, and among skilled and semiskilled workers.

Firm Size

The firm size classification has six categories: (1) *tiny* firms with fewer than 31 workers; (2) *small* firms with 31-300 workers; (3) *medium* firms with 301-500 workers; (4) *large* firms with 501-1,000 workers; and (5) *very large* firms with more than 1,000 workers. We created dummy variables to represent each of these discrete categories.

Occupational Type

The occupational type variable was based on the detailed three-digit Japanese census occupation codes. We grouped detailed occupations into the following nine types: (1) *professional and technical;* (2) *administrative and managerial;* (3) *clerical;* (4) *sales;* (5) *service;* (6) *agricultural;* (7) *skilled;* (8) *semiskilled,* and (9) *unskilled production.*[16] Since our analysis focuses on job mobility of employees in the nonagricultural sector, we exclude transitions that originate from agricultural occupations and use only eight occupational categories. We created dummy variables to represent each of these occupational categories.

CONTROL VARIABLES

Educational Attainment

Education is measured in number of years of formal schooling. In general, we expect workers with higher education to have more resources and assets with which to bargain for better jobs, within and across firms. Educational attainment and credentials commonly set the upper bound on promotions and the pace of promotion schedule, and allocate people to different career tracks. Net of other factors, workers with more education will generally reach higher positions through internal promotions and will follow a faster promotion schedule. Hence, *ceteris paribus,* we expect educational attainment to have a positive effect on the probabilities of within-firm shifts, within and across occupations.

With regard to across-firm transitions, studies in the U.S. have found that educational attainment is positively related to the propensity for interfirm mobility and thus to shorter job and firm tenures (Sandefur 1981). A worker's education is often treated as an indicator of his human capital, or specifically, of his general skills. However, the positive educational effect on within- and across-firm transitions might be confounded with the effects of being a member of a particular occupation, since occupational membership depends on education. So, we need to control education when evaluating occupational effects on men's type of job shift. A positive educational effect (holding occupation constant) would mean that workers in similar occupations who have more educational training tend to have higher relative odds of experiencing a certain type of job shift than another.

Labor Force Experience at the Time of Job Transition

In Japan, seniority-based rewards and age constraints on external recruitment are generally assumed to be common, so we expect a strong negative effect of labor force experience on the across-firm shifts, particularly across occupations, but a positive effect on within-firm job transitions, especially within occupation.

Period When Job Shifts Occurred

We need to control for period effects in our analysis since the time periods during which the job shifts reported in the SSM survey occurred represent periods when the Japanese economy and society underwent drastic changes. We divided the time period into: (1) before 1946 (pre-World War II); (2) 1946-55

(Allied Occupation, economic reconstruction and recovery); (3) 1956-65 (economic expansion); and (4) 1966-75 (further modernization). Considering the rapid economic advancement, acute labor demands, and increased implementation of permanent employment in the late 1960s and early 1970s, we expect an overall trend toward more within-firm movements during the postwar era.

Industry

We need to consider industrial differences in evaluating the effects of occupational and firm labor market structures. Industries, based on the 2-digit census codes, are grouped into seven sectors: (1) mining, (2) manufacturing, (3) finance, (4) trade, (5) communication, (6) service, and (7) government.[17] We control for industry in examining job shift patterns along the occupational and firm dimensions.

Results

Among the 2,169 cases who were employed in the nonagricultural sector, 48% experienced some across-firm, across-occupation job shifts; 22% across-firm but within-occupation shifts; 14% within-firm, within-occupation shifts; and 12% within-firm but across-occupation shifts. Table 2 shows average individual characteristics associated with each type of job shift at the time of transition.

On average, across-firm transitions occur at a younger age than within-firm transitions (about age 28 compared to age 33). This is also reflected in the difference of average labor force experiences at time of transition — about 10 years for across-firm shifts compared to 13 years for within-firm shifts. The discrepancy in terms of tenure between within-firm and across-firm transitions is even greater. Employees who experience within-firm transitions, either within or across occupation, have on average about 10 to 11 years of seniority. For those who move across firms, seniority in the previous firm tends to be much less, around 5.5 years. The majority of within-firm transitions are promotions, particularly those that are also within-occupation (90%),[18] compared to only about a quarter (24% to 28%) of across-firm transitions. Not surprisingly, about half (51%) of across-firm, within-occupation transitions, and 43% of across-firm, across-occupation moves originated from tiny firms with fewer than 31 workers, as compared to about 18% of within-firm type of job shifts. Similarly, while about 30% of both types of within-firm transitions occurred in huge firms with more than 1,000 workers, only 10% of across-firm, within-occupation shifts and 16% of across-firm, across-occupation shifts occurred there.

Workers who make within-firm job moves have a higher mean education than those who make across-firm job moves (12 compared to 10 years of education). Occupations associated with across-firm, across-occupation transitions also, on average, have much less prestige than those associated with within-firm, within-occupation moves. Compared across types, within-firm, within-occupation transitions tend to involve a higher percentage of professionals and technicians than others. On the other hand, across-firm, within-occupation moves have a higher percentage of skilled workers. Within-firm shifts,

TABLE 2: Average Individual Characteristics Associated with Each Type of Job Shift at Time of Transition[a]

	N (Shifts)	Age	Labor Force Experience	Tenure Duration	Education (Year)	Occ. Prestige[b]
Within-firm, within-occupation	361	33.0 (.428)	13.5 (.426)	10.21 (.354)	2.2 (.155)	48.2 (.495)
Within-firm, across-occupation	311	32.6 (.504)	13.4 (.480)	11.2 (.452)	11.8 (.164)	45.1 (.570)
Across-firm, within-occupation	713	28.0 (.333)	10.4 (.300)	5.6 (2.10)	10.5 (.099)	43.4 (.348)
Across-firm, across-occupation	1,632	27.5 (.241)	9.8 (.223)	5.7 (.148)	10.3 (.065)	40.8 (.231)

regardless of whether they are across- or within-occupations, tend to involve clerical types of occupations.

Table 3 presents the results of multinomial logit regression analyses of our hypotheses, and reports contrasts between pairs of mobility types. Coefficient estimates show the effects of the explanatory variables on the relative (log) odds of experiencing a certain type of job transition compared to another, if a worker changes his job.[19] The results for the control variables are consistent with our expectations: education and labor force experience have positive effects on the relative odds of experiencing within-firm shifts (both within- or across-occupation) as opposed to both types of across-firm shifts, and an increasingly higher relative odds of within-firm movements (vs. across-firm transitions) during 1956-1965 and 1966-75 as compared to the prewar era. The only industry that differs involves mining, which facilitates across-firm *within-occupation* (as opposed to across-firm *across-occupation*) transitions, and government, which encourages within-firm, within- or across occupational shifts rather than across-firm within-occupational changes. Overall, the occupational and firm mobility patterns are stable with or without controlling for the period and industry effects.

HYPOTHESIS 1

Consistent with our first hypothesis, Table 3 indicates that men in larger firms are more likely than those in tiny firms (with less than 31 workers) to experience within-firm, as opposed to across-firm, mobility. The firm size effects are quite stable as suggested by the positive coefficients associated with all the within-firm shift versus across-firm shift contrasts (columns 1, 2, 4, and 5). For instance, among those who change jobs, the odds of a worker in a huge firm (1,000+) experiencing a *within-firm, within-occupation* job shift as opposed to an *across-firm, across-occupation* shift (column 1) are 3.0 times higher than those of

TABLE 2: Average Individual Characteristics Associated with Each Type of Job Shift at Time of Transition[a] (Continued)

	Percentage Originated in					Percent Promotion
	Professional	Clerk	Skilled	Tiny Firm	Huge Firm	
Within-firm, within-occupation	12.7 (1.8)	38.0 (2.6)	18.3 (2.0)	17.7 (2.0)	30.7 (2.5)	90.3 (1.6)
Within-firm, across-occupation	4.5 (1.2)	42.4 (2.8)	13.8 (2.0)	18.0 (2.2)	29.1 (2.6)	58.8 (2.8)
Across-firm, within-occupation	6.6 (.9)	16.3 (1.4)	32.1 (1.7)	50.8 (1.9)	10.2 (1.2)	24.2 (1.6)
Across-firm, across-occupation	5.0 (.5)	13.0 (.8)	27.1 (1.1)	42.6 (1.3)	16.0 (0.9)	27.9 (1.1)

[a] Standard errors are in parentheses.
[b] Naoi's occupational prestige scores range from 23.4 to 87.3. (For coding scheme, see Tominaga, Naoi & Imada 1983.)

a tiny-firm worker (exp[1.096]). When contrasted to the probability of an *across-firm*, within-occupation shift, his odds of having a *within-firm*, within-occupation shift instead (column 4) are 6.2 times higher than that of a tiny-firm worker (exp[1.814]). We see similar patterns for the *within-firm*, across-occupation versus *across-firm*, across-occupation contrast (column 2), and the *within-firm, across-occupation* versus *across-firm, within-occupation* contrast (column 5). The relative odds of the first contrast, comparing huge-firm workers to tiny-firm workers, are 2.7 (exp[.976]). As for the second contrast, the ratio is 5.4 (exp[1.694]). Such a tendency of mobility is also evident when comparing big firm (501-1,000) and medium firm (301-500) workers with tiny-firm workers. Even workers in small firms (31-300) have higher odds of having within-firm, as opposed to between-firm, job transitions when compared to tiny-firm workers, although to a lesser extent. These findings support the hypothesis that persons in larger firms are more likely than those in tiny firms to be in FILMs.

HYPOTHESIS 2

The evidence just discussed also provides support for our second hypothesis: men in tiny firms are more likely to change occupations and firms simultaneously than men in larger firms. To obtain relative (log) odds of having across-firm, across-occupation shifts instead of within-firm, within-occupation shifts for workers of different firms, we simply change the sign of the coefficients in column 1.[20] For example, the odds of huge-firm workers having across-firm, across-occupation transitions compared to within-firm, within-occupation shifts

+ $p < 10$ * $p < .05$ ** $p < .01$ *** $p < .001$

are only 33% of those of tiny-firm workers (exp[-1.096] = .334). In reverse, that also means, among those who changed jobs, a tiny-firm worker's odds of having an *across-firm, across-occupation* job shift as opposed to a *within-firm, within-occupation* shift are 3.0 times higher than those of someone originating from a huge firm (exp[1.096]). A similar figure (2.7 = exp[.976], column 2) is obtained for contrast made with *within-firm* but across-occupation shifts. Results in columns 4 and 5 also suggest a consistently higher odds of having *across-firm,* within-occupation type of transitions (contrasted with *within-firm,* within- or

across- occupation transitions) for tiny-firm workers. As opposed to within-firm, within-occupation shifts, their odds of being associated with across-firm, within-occupation transition are about two times those of the small-firm workers, three times the medium-firm workers, five times the big-firm, and six times the huge-firm (exp[.765] = 2.15, exp[.994] = 2.70, exp[1.520] = 4.57), and (exp[1.814] = 6.13, respectively). Similar patterns are observed when relative odds comparisons made between *across-firm, within-occupation* transitions against *within-firm, across-occupation* ones (see column 5). These findings are consistent with our hypothesis that tiny-firm workers are much more likely to be in the unstructured, secondary labor markets (SLAMs).

HYPOTHESIS 3

The data also substantiate the hypothesis that professional and technical employees are more likely than other workers to be in occupational internal labor markets (OILMs). Among men who change jobs, those in professional and technical occupations are less likely than those in unskilled work to change occupations regardless of whether the job shifts are within- or across- firms (Table 3, columns 3 and 6). The odds of professional and technical workers experiencing a within-firm, *within-occupation* transition (as opposed to within-firm, *across-occupation* shift) are about 7.2 times those of unskilled workers (exp[1.970], column 6). Similarly, their odds of experiencing across-firm, *within-occupation* shifts (vs. across-firm, *across-occupation*) are 5.1 times those of unskilled workers (exp[1.634], column 3). In contrast to *across-firm, across-occupation* moves, the odds of professionals and technicians having *within-firm, within-occupation* transitions are 4.7 times higher than those of unskilled employees (exp[1.547], column 1). At the same time, they do not have a higher relative odds of experiencing within-firm, *across-occupation* shifts (vs. across-firm, across-occupation) (column 2). Actually, the relative likelihood for them to make *across-firm, within-occupation* shifts (as opposed to *within-firm, across-occupation*) is significantly higher, about eight times those of unskilled workers (exp[2.056] = 7.8, column 5).

HYPOTHESIS 4

When workers change jobs, managerial and administrative employees have higher odds (about four times, exp[1.276] = 3.58) than unskilled workers of experiencing a *within-firm, within-occupation* transition (vs. *across-firm, across-occupation*) (column 1). This finding seems to suggest that managers and administrators are in FILMs. However, they also tend to stay within the same occupation when moving across firms. Their relative odds of having across-firm, *within-occupation* shifts (vs. across-firm, *across-occupation*) (column 3) are five times higher than the unskilled workers, and similarly are their odds of having *across-firm, within-occupation* shifts (vs. *within-firm, across-occupation*) (exp[1.678] = 5.35 and exp[1.420] = 4.14, column 5, respectively).

HYPOTHESIS 5

Compared to unskilled workers, men in clerical occupations have much higher odds of experiencing both types of intrafirm transitions (within- and across-occupation) as opposed to interfirm, across-occupation transitions (columns 1 and 2). Their relative odds are, respectively, six times and three times greater (exp[1.753] = 5.77 and exp[.946] = 2.58). This is somewhat consistent with our hypothesis that they are in FILMs. However, contrary to our expectation that male Japanese clerks tend to change occupations (becoming managers) as they are promoted within the FILMs, their relative odds of making within-firm, *across-occupation* transitions (vs. within-firm, *within-occupation* shifts) are not higher than those of unskilled workers (in fact, the coefficient, though insignificant, has the opposite sign — see column 6). Moreover, when moving across firms, their relative odds of keeping the same occupation (vs. not) are significantly greater than those of the unskilled (four times, exp[1.476] = 4.38, column 3).

HYPOTHESIS 6

The mobility pattern of skilled workers resembles that of professional and technical workers and substantiate our hypothesis that skilled occupations are likely to be in OILMs. Regardless of whether shifts occurred within or across firms, skilled employees are more likely than the unskilled to remain in the same occupation (columns 3 and 6). Their relative odds of experiencing across-firm, *within-occupation* shifts (vs. across-firm, *across-occupation*), and within-firm, *within-occupation* shifts (vs. within-firm, *across-occupation*), are about three times higher when compared to unskilled workers (exp[1.167] = 3.21 and exp[1.101] = 3.01 respectively). Also, their relative likelihoods of having *across-firm, within-occupation* shifts (vs. *within-firm, across occupation*) are four times higher than those of unskilled workers (exp[1.473] = 4.36, column 5).

HYPOTHESIS 7

Compared to unskilled workers, semiskilled workers have higher odds of across-firm, *within-occupation* transitions: 3.4 times as against across-firm, *across-occupation;* and 6.2 times as against *within-firm, across-occupation* (exp[1.214], column 3, and exp[1.824], column 5, respectively). These findings support our seventh hypothesis that semiskilled workers may also be in OILMs. However, unlike professionals and skilled workers, their relative odds of having *within-firm, within-occupation* moves (vs. *across-firm, across-occupation*) are no higher than those of unskilled workers (column 1); nor do they tend to remain in the same occupation if within-firm shifts ever occur (column 6). They do not seem to be simultaneously in FILMs as are professionals, technicians, and skilled workers.

HYPOTHESIS 8

Our findings are consistent with the hypothesis that unskilled workers are likely to be in SLAMs instead of FILMs. Among job changers, unskilled workers are more likely to have across-firm, across-occupation shifts (as opposed to within-

firm, within-occupation) than men in professional, managerial, clerical, semiskilled production, and service occupations (column 1). Specifically, their relative odds of making across-firm and occupation transitions — versus within-firm and occupation — are about three times those of managers and service workers, five times professionals, and six times clerks (exp[1.276] = 3.58, exp[1.248] = 3.48, exp[1.547] = 4.70, exp[1.753] = 5.77, respectively). Also consistent with our eighth hypothesis is the finding that the odds of unskilled workers changing both firms *and* occupations — versus changing firms but remaining in the same occupation — are much higher than all others except salesmen (column 3). Their relative odds are about three to four times that of semiskilled, skilled, service, and clerical workers, and more than five times that of professionals and managers (exp[1.214] = 3.37, exp[1.167] = 3.21, exp[1.258] = 3.52, exp[1.476] = 4.38, exp[1.634] = 5.12, and exp[1.678] = 5.35, respectively). These facts suggest unskilled workers are likely to be in SLAMs instead of OILMs.

Conclusions

Contrary to the impression often given by popular accounts of Japanese employment relations, our results indicate that Japanese men often do change employers as well as occupations during their careers. Using a conceptualization of internal labor markets that distinguishes between firm (FILMs) and occupational (OILMs) internal labor markets, we tested various hypotheses about how organizational and occupational dimensions were related to four patterns of job shifts.

We found considerable support for our hypotheses. Men in larger organizations were more likely than those in smaller firms to experience within-firm mobility, a pattern consistent with our view that FILMs are more apt to be found in larger firms. Men in tiny firms were more likely to change occupations and firms simultaneously than men in huge firms, suggesting a correspondence between tiny firms and unstructured, secondary labor markets (SLAMs). Workers in unskilled occupations were also apt to be in SLAMs. With regard to OILMs, we found that professional and technical workers were more likely to experience within-occupation mobility. Also suggesting the operation of OILMs were some of our results for managerial and administrative employees, skilled occupations, and semiskilled workers. Moreover, professionals and managers were more likely to have within-firm, within-occupation and across-firm, within-occupation shifts than skilled or semiskilled workers, suggesting high-level white collars in the private sector probably benefit from both types of ILMs. These patterns of job movements are consistent across time periods and industries.

Our findings suggest the utility of systematically examining patterns of job mobility in Japan, rather than relying on simplistic assumptions based on stereotypes of permanent employment or a seniority wage system. With deeper involvements in international trades and operations, and constant needs for product diversification and innovations, large Japanese corporations are under growing pressure to externalize their training and rely more on the external labor market for needed specialized personnel. To accommodate the special

needs of experienced recruits, they inevitably have to modify their employment practices. Considering the aging of the work force and the lower commitment of the younger generation to their employers, the trend toward increased job mobility is prominent. Along with interfirm mobility, we expect that occupation will increase in importance as a work structure shaping labor market processes in Japan.

Future research should compare the mobility of men and women and enrich our quantitative approach with concrete case studies of occupational careers. Studies should also compare Japanese mobility patterns to those in the U.S. and other industrial countries. Our results support the need to reexamine hypotheses about cross-national convergence and divergence in mobility patterns. Research along these lines is likely to enhance markedly our understanding of cross-national variations in the structures and processes of labor market segmentation.

Notes

1. Taira argues that lifetime employment applies only to core employees in private firms with over 500 workers; Marsh and Mannari use the number 1,000. Dore suggests that, in addition to these employees, the system also applies to government firms.

2. Within each industrial sector, relationships between large and small firms are often vertical and unequal in power; large firms dominate small ones through "parent-child" relations in the subcontracting system.

3. The tighter and more far-reaching subcontracting and interlocking relationships between large and small firms are partly historical outcomes of government intervention. In the early and mid-1940s, Japan's military government instituted a controlled economy to support the war efforts. Large firms took in small ones as subcontractors, forming a system of enterprise groupings sustaining the munitions industries (Fujita 1971). After the war, subcontracting was revived and reintroduced as *Kigyo Keiretsu*, an integrated series of companies — a management mechanism to use existing capital and human resources efficiently. In 1955, large enterprises began to dominate small firms by interlocking them through the selective alignment and subcontracting processes (Tatsumi 1971).

4. Other personnel reduction strategies include internal transfer, retraining, and reallocation, layoff of temporary workers and termination of subcontracts, delaying new recruitment, and encouraging early retirements with special pay.

5. Tokunaga (1984) in describing the Japanese labor market structure even suggests that there is "no division of blue-collar workers into 'skilled,' 'semiskilled,' and 'unskilled' categories" (27). In American stratification and mobility studies, by contrast, occupation has been recognized as a major work structure with consequential impact on work life and mobility patterns, and its effect is above and beyond that of organization (e.g., Kalleberg 1983; Kalleberg & Berg 1987).

6. While such a notion is perhaps intuitive in understanding informal group formations among the Japanese, it lacks concrete explanations of how and why the primacy of frame and vertical relations have persisted in the process of industrialization. It has not addressed the facts that, within the same firm, there are different career tracks among workers (e.g., white collars vs. blue collars), and that across firms of various sizes, different labor market structures (e.g., internal vs. external) exist. Although organization affects workers' career prospects and mobility tendency in many important ways, we should not take it as the *sole* factor, particularly when commitment to and identification with one's own firm in fact varies according to firm size, work performance, and occupations (Lincoln & Kalleberg 1990; Mouer & Sugimoto 1986).

7. Government statistics show, over the years 1962 to 1987, the percentage of men who were continuously working but seeking new or additional employment had doubled from 4% to 8%.The percentage wanting to change jobs rose from 4% to 10% (Japan Statistics Bureau 1990). Correspondingly, research studies have reported increases in mid-career recruitment, even for

large-firm regular employee positions (e.g., Watanabe 1987). Beck and Beck (1994) have also captured this mobility trend in their presentations of job movements and intentions of some large-firm, prime-age, top executives.

8. The 1985 SSM survey contains not only men's, but also women's, work data. However, the data have not been made available to foreign scholars. For further details on the sampling procedures and data collection of 1975 SSM survey, see Ishida 1993.

9. Respondents include all persons who reported at least one work history spell (all those who have had some kind of labor force experience).

10. The difference between the two percentages indicates the percentage of respondents who are still with their first employer and have experienced some kind of within-firm job shift (they changed jobs but not employers).

11. Nonjob spells are spells during which respondents are either unemployed, in military service, or have gone back to school. Job spells indicate periods of time in which respondents are actually holding jobs, either as self-employed or as employees.

12. Changing jobs does not necessarily mean changing employers (since this could reflect within-firm job shifts). However, changing employers implies changing jobs. Therefore, men who have had two or more jobs might still work for the same employer.

13. The nonagricultural, employee restriction made here only applies to the state of job origin but not the job shift destination. In other words, the selection of job shifts for analysis is contingent only upon the origin, not the destination. It is conceivable that some of the across-firm shifts accompany a change in employment status, and some across-firm across-occupation shifts involve movements into the agricultural sector.

14. Within- versus across-firm mobility indicates whether or not the job shift is associated with a change in employer. Within- versus across-occupation movements are gauged by using the 288, detailed, three-digit Japanese census occupation codes.

15. For an introduction of multinomial logit models, see Maddala 1983. We use the MLOGIT procedure (SAS version 5.3) to estimate these models.

16. We elaborate the eight-category occupational classification used by the SSM researchers by differentiating "service workers" (identified by the three-digit, 288 occupational titles in the Japanese census classification) from other major categories. The service worker category includes protective service workers (e.g., policemen, firefighters, and guards), domestic, and nondomestic service workers (e.g., cooks, waiters, and garbage collectors). Professionals are researchers, engineers, physicians, lawyers, teachers, artists, etc. Managerial and administrative workers are officials, directors, and managers in public and private enterprises. Clerks engage in accounting, billing, typing, mailing, and other communication. Salesmen are dealers (retail or wholesale), brokers, and sales agents. Agricultural workers include farmers, livestock raisers, foresters, loggers, gardeners, and fishermen. Skilled workers are involved in product manufacturing such as assemblers and repairmen for machines, automobiles, other transportation equipment, precision and optical instruments, and traditional craftsmen making kimonos, tatami, pottery, and traditional food products. Semiskilled workers are machine operators, metal processing workers, electric machine/appliance assemblers and repairmen, and manufacturing workers in textile, paper, wood, rubber, and cement products. Unskilled workers are mostly laborers, diggers, and carriers. The complete occupational classification scheme is available on request from the first author.

17. Two sources in the survey tell whether the respondent was in the government at job change: (1) he was reported as working in a government firm when asked about his employer's firm size (and no further size information is given for a certain government agency), or (2) he was recorded as being in local or national government in the industry question. In either case, we consider this person as being in the government industrial category, and whoever is reported as government industry will not be in other firm size categories except government firm type. The coefficients associated with the dummy government variable can be interpreted as contrasts made to the trade workers (the base category for industry), or to the tiny-firm workers (the base category for firm size).

18. The SSM survey did not ask directly whether each job shift was a promotion. However, it provides some information on the managerial ranking of each of the positions. Here promotion is operationally defined by comparing respondents' positions before and after the job shift. Shifts from ordinary employee rank to any position with a managerial title are considered promotions. Also, managerial titles are hierarchically ranked: (1) department, station, administration directors; (2) section managers, auditors, advisors; (3) branch, store, or office managers; (4) head clerks, chiefs, assistant section managers; and (5) foremen, supervisors. Moving from a lower to a higher level constitutes a promotion, as does shifting from the rank of "foremen/supervisors" to "school principals, deans, directors" or "chief researchers/technicians/editors" in educational, health, or research institutes.

19. In analysis not presented here, we examined this set of hypotheses using a slightly different methodological framework, though we reach strikingly similar conclusions. Using a discrete-time event history approach, we estimated multinomial logistic regression models of the competing risks of the four mutually exclusive types of transitions (within-firm within-occupation, within-firm across-occupation, across-firm within-occupation, and across-firm across-occupation). We allowed each job shift type to have its own hazard function dependence on time (i.e., employment duration) and a similar set of explanatory and control variables. When evaluating the propensities of moving (vs. not moving), we can summarize our findings as follows. Employment duration is positively associated with within-firm transition but negatively with across-firm transition rates. Education is positively related to all shifts except the across-firm across-occupation type. Medium to large firms tend to provide more within-firm opportunities, while huge enterprises and government sector tend to discourage across-firm movements. Compared to unskilled workers, professionals, managers, and skilled workers are much less likely to make across-occupation shifts, within or across firms. While clerks are unlikely to make across-firm across-occupation shifts, they are much more prone to within-firm within-occupation shift. When contrasting the competing risks of making different types of job shifts (e.g., within-firm within-occupation vs. across-firm across-occupation, within-firm across-occupation vs. across-firm across-occupation, etc.), the coefficients associated with the firm size and occupational type variables are very much similar to the results presented here in Table 3.

20. Any pairs of contrast can be made from results shown in Table 3 simply by taking the difference between the coefficients, as long as the original sets of contrasts share the same reference category. For example, coefficients in column 6 can be obtained, within rounding errors, from those in column 1 minus the corresponding estimates in column 2.

Dynamics of Organizational Responses to Competition*

JOEL A.C. BAUM, *University of Toronto*
JITENDRA V. SINGH, *University of Pennsylvania*

Abstract

This research examines how processes of adaptation and selection operate jointly in the evolution of a population of day-care centers (DCCs) in metropolitan Toronto. We study how DCCs alter their organizational niches, defined by productive capacities and targeted resources, in response to competition and how these changes influence their survival chances. Exhibiting little structural inertia, DCCs modified their organizational niches in response to changing competitive conditions, often without any harmful effects. Indeed, DCCs that moved to less competitive organizational niches improved their survival chances. At the same time, however, competition increased rates of DCC failure and the organizational niche changes made by DCCs did not, on average, affect either the intensity of competition they faced or their longevity. We discuss the implications of these findings, which indicate that the evolution of the DCC population is a joint function of adaptation and selection processes.

The nature and consequences of change among existing organizations and the manner in which populations of organizations and industries evolve over time underlie a current polemic for researchers in organization theory. Although adaptation theories vary in the extent to which they rely on the rational calculation and the capabilities of organizational actors, most suggest that relatively pliable organizations commonly respond to threats and opportunities created by environmental change by altering organizational strategies and structures in ways that enhance performance and prospects for survival (e.g., Chandler 1977; Pfeffer & Salancik 1978; Porter 1980; Rumelt 1986; Thompson 1967). Consequently, for adaptationists, variability among organiza-

 Social Forces, June 1996, 74(4):1261-1297

tions over time reflects the cumulative changes of individual organizations. In contrast, selection theories depict organizations as relatively inert entities for which adaptive response is not only difficult and infrequent, but hazardous as well (Amburgey, Kelly & Barnett 1993; Hannan & Freeman 1977, 1984). Consequently, for selectionists, organizational variability is primarily a reflection of relatively inert organizations replacing each other.

Although adaptation and selection theories are often portrayed as mutually exclusive alternatives with distinct implications (Scott 1992), they are sometimes seen as complementary (Bourgeois 1984; Child 1972; Hrebiniak & Joyce 1985; Levinthal 1991). Building upon their potential complementarity, researchers have begun to examine organizational flexibility empirically and to model the adaptiveness of organizational change dynamically (for a review, see Baum 1996).

The purpose of this study of organizational niche changes (i.e., moves by ongoing organizations within a resource space) in a population of day-care centers (DCCs) in metropolitan Toronto is to extend research specifying how processes of adaptation and selection jointly influence organizational evolution in two ways. First, we examine the influence of organizational niche overlap and nonoverlap on rates at which DCCs change organizational niches. Second, we study the adaptiveness of organizational niche changes by examining whether DCCs that move to organizational niches with less intense competition have different fates than those that change to organizational niches where competition is more intense. Despite the centrality of competition to adaptationist and selectionist accounts of organizational change, research on the dynamics of organizational change has not yet examined how the consequences of organizational change are related to their effects on the intensity of competition.

This study is part of a research program in which we investigate the implications of organizational niches for understanding population dynamics. In addition to the "macro-niches" of organizational populations (Hannan & Freeman 1977, 1989), organizations have their own "micro-niches" defined by the intersection of resource requirements and productive capacities at the organizational level (McKelvey 1982:109-10). Thus, the macro-niches of organizational populations encompass multiple organizational niches. In our research, we define the organizational niches of DCCs on the basis of a critical resource dimension: the ages of children DCCs are licensed to enroll. We measure organizational niche change as the expansion or contraction of the range of ages DCCs are licensed to enroll. Organizational niche changes, which are moves by organizations within the macro-niche, entail organization-level changes in organizational capabilities and assets.

In earlier studies (Baum & Singh 1994a, 1994b), we found that, because DCCs operating in different organizational niches face different competitive landscapes, different patterns and rates of founding accompany different choices of organizational niche at founding and that, after founding, DCCs occupying different organizational niches endure different fates. The theoretical arguments in this article broaden the scope of our work to include organizational niche change and its survival consequences.

For multiple reasons, DCC organizational niche change provides a useful mechanism by which to investigate organizational responses to competition and

their survival consequences. Previous studies of DCC founding and failure established that competition plays a significant role in the dynamics of this population (Baum & Singh 1994a, 1994b). Organizational niche change is the main way DCCs change their core features — the claims they stake for themselves in terms of the clients they target, the services they have the capacity to provide, the complexity and differentiation of internal organization, the human and material resources they employ, and their linkages with clients and the external environment. Therefore, organizational niche change represents a potentially disruptive form of change that selectionist theory suggests will subject DCCs to a significant risk of failure in the short run (Hannan & Freeman 1984). The typical smallness of DCCs reinforces further their high risk of death from change (Hannan & Freeman 1984). On the other hand, adaptationist theories view organizational niche changes as pervasive, planned, and adaptive responses to competition that influence organizational success (Fligstein & Dauber 1989; Miles & Snow 1978; Porter 1980; Ramanujam & Varadarajan 1989; Rumelt 1986). Indeed, given the organizational simplicity of DCCs and their environments, one might expect them to possess a high potential for developing adaptive responses to competition.

Organizational Responses to Competition

In organizational ecology, the potential for competition among organizations is predicted mostly to be a function of similarity in resource requirements: the more similar the resource requirements, the greater the potential for intense competition (Hannan & Freeman 1977, 1989; McPherson 1983). At one extreme, organizations with identical resource requirements are perfect competitors. At the other, organizations with resource requirements that do not intersect at all do not compete. In general, the potential for competition between any two organizations is directly proportional to the overlap or intersection of their organizational niches. More formally, the potential for competition between two organizations in two organizational niches i and j can be represented by an *organizational niche overlap weight*, w_{ij}, that varies between 0 (i.e., no overlap in organizational niches and no potential for competition) and 1 (i.e., complete overlap in organizational niches and a high potential for competition) (McPherson 1983). The organizational niche overlap weight, w_{ij}, which gives the potential competition experienced by an organization in organizational niche i resulting from the presence of an organization in organizational niche j, is equal to the proportion of the resources of organizations in organizational niche i that are also required by those in organizational niche j. This ecological approach gives a quite simple way of measuring the potential competition for the underlying resources between different members of an organizational population or industry.

OVERLAP DENSITY

For every organization, we define a variable, *overlap density,* which captures the potential competition faced by that organization. Overlap density measures the potential for competition by aggregating the organizational niche overlaps of a focal organization with those of all other members of its population. More formally, the overlap density for an organization in organizational niche i at time t is given by

$$\textit{Overlap Density}_{it} = N_{it} + \sum_{j \neq i} w_{ij} N_{jt}, \tag{1}$$

where N_{it} is the number of population members in organizational niche i at time t, N_{jt} is the number of organizations in organizational niche j at time t, and w_{ij} is the organizational niche overlap weight for organizations in organizational niche i with those in organizational niche j. Earlier research shows that increases in overlap density have competitive effects that lower rates of founding and increase rates of failure (Baum & Singh 1994a, 1994b). In this article we examine the effects of overlap density on rates of organizational niche change.

How do organizations respond to competition? Swaminathan and Delacroix (1991) suggest that organizations do not normally respond to competition by *dying* (Hannan & Freeman 1977, 1989) but by engaging in search for alternative ways to sustain themselves. Kelly and Amburgey's (1991) study of the U.S. airline industry led them to conclude similarly that managers may possess more discretion regarding change than selectionists typically propose. Following Hawley (1950), Swaminathan and Delacroix argue that organizations become differentiated as competition pushes less fit competitors out of the market, and losing organizations are transformed either through territorial or functional differentiation by entrepreneurs seeking out distinct functions in which they hold a competitive advantage. Recently, this view has been supported in studies of the California wine industry (Delacroix, Swaminathan & Solt 1989; Swaminathan & Delacroix 1991), providing evidence that differentiation occurred in response to competition and that lateral migration into a neighboring market niche (table wines) lowered failure rates for California wineries. Singh, Tucker, and Meinhard's (1991) finding that rates of change in a population of voluntary social service organizations responded to changes in both institutional and competitive conditions, and Haveman's (1994) finding that diversification activities of California S&Ls were responsive to changes in the competitive environment further corroborate this position.

Since greater overlap density implies greater interorganizational competition for resources, the adaptationist view implies that overlap density is positively related to the intensity of search by organizations for alternative ways to sustain themselves. Both expansion and contraction of an organization in the niches it occupies may serve as responses to the problem of increased competition: diversification into new market segments can moderate the effects of competition and withdrawal from a market segment can avoid competition. Therefore, we hypothesize:

Hypothesis 1. Overlap density is positively related to the rate of organizational niche expansion and contraction.

NONOVERLAP DENSITY

Whereas overlap density captures the potential for competition between organizations by aggregating resource overlaps, the difference between overlap density and population density (Hannan & Freeman 1989) is the aggregate of the resource nonoverlaps. We refer to this difference as *nonoverlap density* (Baum & Singh 1994a, 1994b). Nonoverlap density is an estimate of the number of organizations whose resource requirements do not overlap with those of the focal organization. Thus, for each organization, overlap density aggregates the organizational niche overlaps with all other organizations in the population and captures the potential for competition, and nonoverlap density aggregates the organizational niche nonoverlaps and captures information about noncompeting organizations. In terms of equation 1

$$\textit{Nonoverlap Density}_{it} = N_t - [N_{it} + \sum_{j \neq i} w_{ij} N_{jt}], \qquad (2)$$

where N_t is the number of organizations in the population (i.e., population density) at time t and all other terms are as defined in equation 1.

For organizations considering organizational niche expansion, nonoverlap density provides information on potential competition in market segments into which they might diversify. Mitchell (1989) showed how such potential competition lowered rates of entry into emerging subfields by incumbent firms in the U.S. diagnostic imaging industry. Haveman (1994) found similar effects of potential competition on rates of entry by California S&Ls into new markets. Since greater nonoverlap density implies greater potential competition for resources in *other* market segments that may be opportunities for expansion, we expect nonoverlap density to be negatively related to rates of organizational niche expansion.

Our expectations about the effect of nonoverlap density on rates of market contraction are based on a quite different logic. Differentiation that separates organizational resource requirements reduces competition (Baum & Mezias 1992; Chamberlin 1933; Delacroix, Swaminathan & Solt 1989; Hannan, Ranger-Moore & Banaszak-Holl 1990). In addition, differentiation can create complementary functional differences between organizations (Barnett 1990; Barnett & Carroll 1987; Fombrun 1986; Hawley 1950). When such differences arise, they can lead to direct mutualistic relations among organizations. For example, DCCs licensed to enroll infant children may create future demand for those licensed to enroll toddlers. Or they can cooperate directly by referring potential customers to each other. Nonoverlap density may also produce diffuse mutualism by capturing information about the widening social acceptance of the organizational form itself (Hannan & Carroll 1992; Hannan & Freeman 1989). Given the lack of competition for the underlying resources and the potential facilitative effects of mutual demand enhancement and the widening social acceptance of the organizational form, we expect nonoverlap density to foster mutualistic relations among organizations. Supporting this expectation, earlier research shows that increases in nonoverlap density increase rates of DCC founding and lower rates of DCC failure (Baum & Singh 1994a, 1994b). We expect that the mutualism produced by increases in nonoverlap density will help sustain organizations in their current organizational niches, reducing the

need for withdrawal from a market segment. Based on these arguments and this evidence, we hypothesize

Hypothesis 2. Nonoverlap density is negatively related to the rate of organizational niche expansion and contraction.

Competition, Organizational Change, and Failure

Research on organizational change in organization and management theory often focuses on the content of changes: A change to a more advantageous configuration is considered as adaptive, while a switch to a less advantageous configuration is considered detrimental (Amburgey, Kelly & Barnett 1993). Complementing this focus on content, Hannan and Freeman's (1984) structural inertia theory offers a model of the process of organizational change that considers both internal and external constraints on change.

STRUCTURAL INERTIA THEORY

Perhaps the most striking aspect of structural inertia theory is the relationship proposed between organizational change and the liability of newness, the propensity of young organizations to have higher failure rates (Stinchcombe 1965). Hannan and Freeman (1984) propose that some changes produce a renewed liability of newness by robbing an organization's history of survival value. Change renews an organization's liability from newness when it reshuffles work groups, reshapes communication lines and role relationships, and requires the use of new or altered operating routines. Such change renders obsolete an organization's accumulated skills, roles, and routines, reducing its reliability of performance back toward that of a new organization. Changes that upset an organization's exchange relationships with the environment or raise questions about its legitimacy can also reset an organization's liability-of-newness-clock and raise its failure rate.

However, Hannan and Freeman (1984) do not expect the disruptive effects of a given change to be the same for all organizations. Organizational age and size are both predicted to affect the likelihood of surviving the short-run shock of a core change attempt. Because their internal structures and routines are more institutionalized and their external linkages are better established, older organizations are especially likely to experience disruption as a result of core change. In contrast, larger organizations, although less likely to attempt core changes in the first place, are less likely to die during a core change attempt. Largeness can buffer organizations from the disruptive effects of core change by helping, for example, to maintain both old and new ways of doing things during the transition or to overcome short-term deprivations and competitive challenges that accompany the change attempt.

From these arguments, Hannan and Freeman (1984) conclude that, frequently, actions to promote survival expose organizations to a short-run increased risk of failure equivalent to a liability of newness. However, if an organization survives the short-run shock of change, the risk of failure is expected to decline with the passage of time as performance reliability is reestablished, external relationships are restabilized, and organizational

legitimacy is reaffirmed. If decline in the death rate subsequent to the change continues at a rate identical to that before the change, the organization will face the short-term risk of change without any long-term benefit. But if the decline in the death rate after the change is slower than before, the organization will increase both its short-term and long-term risk of failure. Only if the decline is faster than the original rate will the organization benefit in the long run from taking on the short-term risks of change. Thus, from a selection perspective, although organizational change is viewed as disruptive in the short run, it can, ultimately, be adaptive in the long run if the organization manages to overcome the problems associated with the initial disruption (Amburgey, Kelly & Barnett 1993).

Supporting structural inertia theory predictions, in a study of the effects of organizational change on rates of failure in the Finnish newspaper industry, Amburgey, Kelly, and Barnett (1993) found detrimental short-run effects on organizational survival for changes in content and publication frequency that declined as the change receded into the past. Amburgey, Kelly, and Barnett also found that the disruptive effects of changes in content and publication frequency increased with the age of newspaper organizations. Lacking information on organizational size, Amburgey, Kelly, and Barnett could not examine size variation in the disruptive effects of change. In a comparable study, of presidential and managerial succession in the early Iowa telephone industry, Haveman (1993) found detrimental short-run effects of leadership succession on organizational survival that declined as the succession receded into the past. However, the disruptive effects of leadership changes did not increase with the age of telephone companies. Although Haveman did have information on organizational size, she did not examine size variation in the disruptive effects of succession. And, finally, in a study of California wineries, Delacroix and Swaminathan (1991) found no evidence of detrimental effects for brand and product changes in either the short or long run, although they did not examine either age or size variation in the disruptive effects of brand and product changes. Given the scarcity, equivocality, and incompleteness of previous tests of Hannan and Freeman's (1984) predictions, we test the following hypotheses about immediate and dynamic effects of organizational niche change on the rate of failure, which capture the structural inertia theory specification more fully:

Hypothesis 3. The failure rate increases immediately after organizational niche expansion or contraction but declines with the passage of time.

Hypothesis 4. The disruptive effects of organizational niche expansion and contraction increase with the age of the organization.

Hypothesis 5. The disruptive effects of organizational niche expansion and contraction decrease with the size of the organization.

EFFECTS OF CHANGE ON COMPETITION

The emphasis of structural inertia theory on change processes has resulted in less attention being given by ecological researchers to the content of changes. Although ecological researchers do differentiate broad categories of changes according to their content (e.g., content versus frequency change, brand versus

product change, presidential versus managerial change), all instances of a particular category of change are assumed to have the same effect on organizational survival. However, there may be within-category differences in change content that alter their survival implications markedly. One such within-category difference is variation in the effects of changes on competition. Do the disruptive effects of organizational niche changes depend on how they influence the intensity of competition that organizations face?

We propose that changes to organizational niches in which competition is more intense will be detrimental to prospects of organizational survival and that changes to organizational niches in which competition is less intense will improve organizational survival chances. Shifting to a more competitive organizational niche may increase the risk of failure for several reasons. Intense competition creates resource scarcity (Carroll & Hannan 1989). When resources are scarce, organizations cannot move quickly to full-scale operation and may find it difficult to minimize performance disruptions by, for example, maintaining both old and new ways of doing things during periods of transition. Intense competition also results in tight niche packing (Carroll & Hannan 1989). When organizational niches are crowded, few resources go unexploited. This forces new entrants, which are at a disadvantage in head-to-head competition with incumbents, to use inferior or marginal resources, making new client relationships more difficult to establish. Organizations that move into more competitive organizational niches may also be more vulnerable to questions about organizational legitimacy resulting from changes in their visible missions. These deprivations and challenges during the initial period after a change into a more competitive organizational niche may be difficult to recover from and, as a result, may affect the viability of the organization throughout its existence (Carroll & Hannan 1989). Thus, moving into a more competitive organizational niche may magnify the disruptive effects of change, while moving into a less competitive organizational niche may moderate any disruption. Since, as we discussed earlier, greater overlap density implies greater competition, we expect moves to organizational niches with higher levels of overlap density to increase failure rates.[1]

Hypothesis 6. The failure rate is positively related to increases in overlap density that result from organizational niche expansion and contraction.

Research Methods

DATA DESCRIPTION

We compiled life history information from two sources on all licensed DCCs in metropolitan Toronto from 1971 to 1989. The Community Information Center of Metropolitan Toronto's *Directory of Day Cares and Nursery Schools,* published yearly since 1971, provided detailed information on all DCCs in metropolitan Toronto. The Ontario Ministry of Community and Social Services' *Day Nurseries Information System,* which, starting in 1979, contains annual licensing records for all DCCs in Ontario, provided a cross reference to the *Directory*. Between 1971 and 1989, 682 DCCs were founded. The founding date was defined as the year in which the original operating license was issued by the ministry or the year

of first appearance in the *Directory*. Of the DCCs founded since 1971, 139 ceased operations by the end of 1989. The failure date was defined as the first year of reported closing in the ministry archives or *Directory*. At the start of 1971, there were 109 DCCs in metropolitan Toronto. Of these left-censored DCCs, 39 failed by the end of 1989. Through telephone interviews and searches of the Ontario Incorporation Indexes and telephone directories, founding dates were verified for all but two left-censored DCCs. Therefore, the analysis included 789 DCCs, of which 176 failed during the observation period.

DCC Organizational Niches

DCCs in metropolitan Toronto are licensed by the Ministry of Community and Social Services to provide full-time, collective care to five or more children in one or more of the following age ranges: *infant*, birth to 18 months; *toddler*, 19-30 months; *preschool*, 31-60 months; and *school-age*, 61-120 months. DCCs are free to become licensed in any or all age ranges but must pass an inspection performed by provincial authorities to ensure that specified licensing criteria are met before enrolling children in a particular age range. In addition to varying in the ages of children they may legally enroll, DCCs serving children of different ages also differ on a variety of organizational dimensions. To obtain a license to serve a given number of children in a particular age range, a DCC must possess a particular configuration of staff, program, equipment, and facility requirements geared to the developmental needs of children in the age range. Therefore, the configurations of human and material resources possessed by DCCs differ according to the age ranges served. DCCs licensed in more than one age range are required to allocate these configurations of resources exclusively to the care of children in the specified age groups. As a result, DCCs licensed in several age ranges possess more diverse and complex configurations of human and material resources. Thus, a DCC's licensed age ranges provides information on its care-giving capabilities as well as its formally targeted client-market domains. Using information on licensed ages ranges, we identified ten DCC organizational niches. Table 1 shows the number of DCCs occupying each organizational niche in each observation year.[2]

DCC Organizational Niche Expansion and Contraction

For DCCs, we define organizational niche expansion as the addition of a new licensed age range and organizational niche contraction as the withdrawal from a previously licensed age range. Organizational niche expansion requires new investments in human and material resources to meet licensing requirements.[3] Organizational niche expansion also requires DCCs to cope with additional burdens of increased diversification including increased structural complexity, greater human and material resource diversity, and a broader and more complex task environment. Organizational niche expansion also requires DCCs to cultivate new market linkages, communicate new organizational goals to key stakeholders, and be cautious in how they allocate slack resources. By comparison, organizational niche contraction lowers the cost of maintaining a DCC, reduces organizational and environmental complexity, and potentially frees resources for alternative uses. Organizational niche contraction may therefore

[a] Organizational niches:
I = Infant, 0-18 months
T = Toddler, 19-30 months
P = Preschool, 31-60 months
S = School-age, 61-120 months
TPS = 19-120 months
TP = 19-60 months
PS = 31-120 months
ITP = 0-60 months
IT = 0-30 months
ITPS = 0-120 months.

[b] DCC: Total number of organizations

serve as a cost-reduction measure for DCCs unable to maintain wide organizational niches (i.e., more diversified strategies). However, because it disrupts child care for some families, organizational niche contraction is likely to provoke questions from a DCC's constituents about its legitimacy, accountability, and future reliability.

Thus, organizational niche expansion and contraction alter the core features of DCCs (Baum 1990) — the claims they stake for themselves in terms of the clients they target, the services they have the capacity to provide, the complexity and differentiation of internal organization, the human and material resources they employ, and their linkages with the external environment. Notably, organizational niche expansion appears likely to produce both internal and

external disruptive implications for DCCs, while the disruptive effects of organizational niche contraction appear primarily external.

From archival information, the organizational niche expansion and contraction activities of each DCC were noted annually in its historical data record. DCCs underwent 277 organizational niche expansions and 147 organizational niche contractions during the observation period. It is indicative of the significance of organizational niche changes for DCCs that, although these changes occurred with moderate frequency in the population, most DCCs underwent few, if any, changes. In addition, all changes involved either the addition or the deletion of a single age range adjacent to those already served. Table 2 shows the frequency of expansions and contractions by origin and destination organizational niches.

ANALYSIS

We tested the hypotheses using parametric models of organizational change and failure. A multivariate point-process approach (Amburgey 1986) was used to model the competing risks of organizational niche change and failure. In the analysis, organizational niche expansion, contraction, and failure were modeled as competing risks. In other words, in each year of its existence a DCC was treated as having a competing risk of expanding its organizational niche, contracting its organizational niche, or disbanding. Operationally, we specified each marginal process in terms of the instantaneous transition rate:

$$r_{jk}(t) = \lim q_j(t, t+\Delta t)/\Delta t, \tag{3}$$

where q_j is the discrete probability of organization j experiencing event type k (i.e., expansion, contraction, or failure) between t and $t + \Delta t$, conditional on being at risk for the event at t. Rate models have the advantages of being flexible in specification and reducing the effects of the right-censoring problem (Tuma & Hannan 1984). The models we estimated were of the following general form

$$r_k(t) = \exp\ (\beta_k X_t), \tag{4}$$

where X_t is a vector of the values of the time-varying covariates and β_k is a vector of parameter estimates indicating the effects of the covariates on the rate of occurrence. In this model, rates of change and failure are assumed to be loglinear functions of the covariates, which precludes negative predicted rates. We used *RATE* (Tuma 1980) to estimate the vector of parameters β_k by the method of maximum likelihood.

Since DCCs licensed in all four age ranges cannot, by definition, expand their organizational niches, the sample for the analysis of organizational niche expansion includes only DCCs at risk of expanding their organizational niches between t and $t + \Delta t$ (i.e., licensed in three or fewer age ranges). Conversely, since DCCs licensed in only one age range cannot, by definition, contract their organizational niches, the sample for the analysis of organizational niche contraction includes only DCCs at risk of contracting their organizational niches between t and $t + \Delta t$ (i.e., licensed in two or more age ranges).

TABLE 2: DCC Organizational Niche Expansions and Contractions by Organizational Niche[a]

To Org. Niche j[b]	From Organizational Niche i[b] I	T	P	S	IT	TP	PS	ITP	TPS	ITPS
I					(2)					
T					(2)	(5)				
P						(17)	(50)			
S							(9)			
IT	5	4						(3)		
TP		7	40					(5)	(16)	
PS			87	16					(12)	
ITP					9	23				(18)
TPS						17	34			(8)
ITPS								14	21	

[a] Numbers in parentheses are frequencies of organizational niche contractions.
[b] Organizational niches:

I = Infant, 0-18 months	TP = 19-60 months
T = Toddler, 19-30 months	PS = 31-120 months
P = Preschool, 31-60 months	ITP = 0-60 months
S = School-age, 61-120 months	TPS = 19-120 months
IT = 0-30 months	ITPS = 0-120 months.

INDEPENDENT VARIABLES

Overlap Density and Nonoverlap Density

To test hypotheses 1 and 2, we computed values for overlap density and nonoverlap density for each DCC in each year using equations 1 and 2. Values for overlap density were computed by summing yearly values for the number of DCCs in an organizational niche (see Table 1) multiplied by the appropriate organizational niche overlap weights, w_{ij} (see Appendix B). For example, using equation 1, the overlap density (rounded to the nearest number of competitors) for DCCs in the infant-toddler (IT) organizational niche in 1981 is

$$Overlap\ density_{(IT)1981} = (.6 \times 1_I) + (.4 \times 1_T) + (1 \times 10_{IT}) + (.4 \times 9_{TP}) + (1 \times 14_{ITP}) + (.4 \times 11_{TPS}) + (1 \times 8_{ITPS}) = 41$$

where $N_I \ldots N_{ITPS}$ are the number of DCCs in each organizational niche in 1981. The value for nonoverlap density equals the difference between the total number of DCCs and overlap density (347 - 41 = 306). Yearly values for overlap density for all organizational niches are given in Appendix C. Since earlier research has shown that overlap and nonoverlap densities significantly influence failure rates in the DCC population (Baum & Singh 1994a), we also include these variables in the failure analysis.

Local and Diffuse Overlap and Nonoverlap Densities

In the DCC population, clients tend to come from geographically contiguous areas at a higher rate than from distant places. Since day-care services are provided on the premises of DCCs, parents must transport their children to and from DCCs daily. This transportation cost localizes demand, partitioning the market for day care into numerous local geographic segments. As a result, the location of a DCC influences the potential for organizational niche-based competition among DCCs (Baum & Singh 1994a, 1994b). Therefore, we computed separate local and diffuse measures of overlap density and non-overlap density based on the geographic location of a DCC within metropolitan Toronto. Local densities were calculated for each DCC using information on DCCs operating in the same constituent city of metropolitan Toronto as the focal DCC.[4] Conversely, diffuse densities were computed using information on DCCs operating in all other constituent cities.

Organizational Niche Change and Time-Clock Variables

To model the immediate and dynamic effects of organizational niche changes on rates of DCC failure predicted in hypothesis 3, we followed the procedure outlined by Amburgey, Kelly, and Barnett (1993) and used by Delacroix and Swaminathan (1991). First, we created two dummy variables. The first dummy variable was set equal to zero until the occurrence of an organizational niche expansion. Thereafter, the variable was set equal to one. The second dummy variable was constructed in a similar manner from the occurrence of organizational niche contractions. In addition, we created two time-clock variables to track the elapsed time since a DCC last expanded or contracted its organizational niche. The time-clock variables were set equal to zero until an organizational niche change of either type occurred. After an organizational niche expansion, the organizational niche expansion time-clock variable measured the natural logarithm of the number of years since the change occurred. The counter was reset after any subsequent expansions. The organizational niche contraction time-clock variable was derived in an identical manner from the occurrence of organizational niche contractions. In combination, the organizational niche change and time-clock variables capture the immediate and longer-term effects of organizational niche changes on the risk of DCC failure, permitting the short-term and longer-term effects of organizational niche changes to be different.

To test hypothesis 4, following Amburgey, Kelly, and Barnett (1993), we allowed the dummy variables for organizational niche expansion and contraction to interact with organizational age. These interactions equal zero before the first change and equal organizational age thereafter. If the first change occurs early on, age is lower and the change in the failure rate smaller; if the first change occurs later on, age is higher and the failure rate is greater. To test hypothesis 5, we allowed the dummy variables for organizational niche expansion and contraction to interact with organizational size at the time of the change. These interactions equal zero before the first change and equal organizational size at the time of the change thereafter.

Overlap Density Change

To test hypothesis 6, we calculated the change in the intensity of competition resulting from each organizational niche change. We did this by comparing values of overlap density for a DCC's new and old organizational niches at the start of the year in which it changed. The effects of organizational niche changes on overlap density are a joint function of the resulting changes in organizational niche width and in the resource overlaps with potential competitors. For example, expanding from the preschool (P) organizational niche into the preschool-school-age (PS) organizational niche in 1985 would change overlap density as follows:

$$\textit{Overlap density}_{(P)1985} = (1 \times 154_P) + (1 \times 40_{TP}) + (1 \times 115_{PS}) + (1 \times 29_{ITP}) + (1 \times 23_{TPS}) + (1 \times 9_{ITPS}) = 370$$

$$\textit{Overlap density}_{(PS)1985} = (.33 \times 154_P) + (.67 \times 87_S) + (.33 \times 40_{TP}) + (1 \times 115_{PS}) + (.33 \times 29_{ITP}) + (1 \times 23_{TPS}) + (1 \times 9_{ITPS}) = 279$$

where $N_I \ldots N_{ITPS}$ are the number of DCCs in each organizational niche in 1985 (see Table 1). Overall, the move from preschool to preschool-school-age adds 87 potential school-age (S) competitors but, by increasing the organizational niche width from 30 months to 90 months (see Appendix A), lowers the resource overlaps with DCCs in all organizational niches other than those that include both the preschool and school-age ranges.

Using information on the effects of organizational niche changes on overlap density, we created two variables. The first variable, *Δ overlap density (expansion),* was set equal to zero until the occurrence of an organizational niche expansion. Thereafter, the variable was set equal to the change in overlap density resulting from the expansion. After any subsequent expansion, the variable was reset to the value of the new change in overlap density. The second variable, *Δ overlap density (contraction),* was constructed in a similar manner from the changes in overlap density resulting from organizational niche contractions. We also computed separate variables to capture the effects of organizational niche changes on local and diffuse overlap densities.[5]

CONTROL VARIABLES

To rule out plausible alternative explanations we also controlled for the effects of several organizational characteristics and the environmental carrying capacity.

Organizational Characteristics

Organizational age was defined as the natural logarithm of the number of years since the year of founding. *Organizational size* was measured for each DCC in each year as the natural logarithm of the licensed capacity specified in its annual operating license, which sets the maximum number of children that a DCC can enroll legally. We also included changes in the licensed capacity of each DCC (lagged by one year) in the analysis. Because these changes may reflect discrepancies between demand for services and organizational capacity, this variable may also capture some effects of recent performance on rates of change and failure (Scott 1992). The *profit orientation* of DCCs was also controlled using a dummy variable coded 1 for nonprofit DCCs and zero for profit-

oriented DCCs because influential institutional actors and the public in general have increasingly opposed for-profit child care in metropolitan Toronto and elsewhere in Canada (Maynard 1985).

We also controlled for two kinds of institutional linkages, *purchase-of-service agreements* (POSAs), which link DCCs to the Metropolitan Toronto Children's Services Division (CSD), and *site-sharing arrangements* (SSAs), which involves operating in space leased from or provided by community-based organizations including community centers, schools, and churches. These linkages can influence rates of organizational change and failure by conferring legitimacy and more specific resources on organizations (Baum & Oliver 1991; Miner, Amburgey & Stearns 1990). The effects of POSAs and SSAs were controlled with two dummy variables coded one for DCCs with POSAs or SSAs and zero otherwise.

To control for the possibility that organizational experience with a particular type of change increases the probability of repeating the change but that the probability declines as the change recedes into the past (Amburgey, Kelly & Barnett 1993; Delacroix & Swaminathan 1991; Ginsberg & Baum 1994), we created two variables to count the cumulative occurrence of organizational niche expansion and contraction. These variables were set equal to zero until the first change, 1 until the second change, 2 until the third change, and so on. To control for the time-lapse effect, we included the organizational niche change time-clock variables described above in the change models.

We also control for variation in rates of change and failure by organizational niche using four age-range dummy variables. For each year of a DCC's existence, the dummy variables corresponding to the age ranges it was licensed to serve were coded 1. All others were coded zero. Finally, to examine if left-censored DCCs had systematically different rates of change and failure, a dummy variable coded 1 for DCCs founded before 1971 and zero otherwise was included in the analysis.

Environmental Carrying Capacity

We estimated the demand for DCCs licensed to enroll children in age range i in location j on a yearly basis using the following equation:

$$Demand_{ij} = EN_{ij} + \%WW(NC_{ij} - EN_{ij}) + \%SP[(NC_{ij} - EN_{ij}) \times (1 - \%WW)] \quad (5)$$

where $Demand_{ij}$ is the estimated annual demand for DCC services in age range i in location j, EN_{ij} is the number of children in age range i in location j that are enrolled in a DCC, $\%WW$ is the percentage of women residing in metropolitan Toronto that participate in the work force full-time, NC_{ij} is the total number of children in age range i in location j, and $\%SP$ is the percentage of children from birth to 10 years of age in metropolitan Toronto that reside in single-parent households.[6] In the equation, demand comprises three additive components: the number of children enrolled in DCCs; the number of children with working mothers not enrolled in DCCs; and the number of children living in single-parent households not enrolled in DCCs. We weight the final component by ($1 - \%WW$) since the vast majority of single parents in metropolitan Toronto are working women (City of Toronto Planning and Development Department 1983; Social Planning Council of Metropolitan Toronto 1981). Thus, the demand equation weights the number

of children by factors related to the likelihood that they will require day care. The annual estimates for each age range in each location were used to construct estimates for total and local organizational niche demand for each DCC based on the age ranges it was licensed to enroll at the start of each year and its geographic location. To control for a possible *demand-pull* effect on rates of organizational niche change, we also included a variable measuring the demand for services in the age range(s) each DCC was not licensed to serve at the beginning of each year.

In addition, we controlled for (1) the interest rate for small business loans, (2) the value of the Children's Services Division budget in constant dollars, which measures the government resources provided to parents in need for purchasing services from DCCs with POSAs, (3) the number of early childhood education graduates from Ontario community colleges, which represent the pool of new labor for DCCs that meets the staff qualification requirements, and (4) the number of foundings and failures in a DCC's organizational niche in the prior year in the failure models (Delacroix, Swaminathan & Solt 1989).

Results

ORGANIZATIONAL NICHE CHANGE

Table 3 reports the maximum-likelihood estimates for the analysis of rates of DCC organizational niche expansion and contraction. Models 1 and 2 estimate the effects of overlap density, nonoverlap density, and the organizational and environmental control variables on the rate of organizational niche expansion and contraction, respectively. Supporting hypotheses 1 and 2, the rate of organizational niche expansion increased significantly with increases in overlap density and declined with increases in nonoverlap density. Thus, DCCs were *pushed* into new market segments by competition in their current organizational niche and *pulled* into new market segments by the prospect of low potential competition in the new market segment. The estimates for organizational niche contraction in model 2 provide only partial support. Contrary to hypothesis 1, the rate of organizational niche contraction is negatively related to overlap density. However, hypothesis 2 is supported by the significant negative estimate for the effect of nonoverlap density on the rate of contraction. Thus, DCCs responded to increasing competition by expanding their organizational niches but not by contracting them. One possible explanation for this finding is that in a competitive environment, contraction hampers a DCC's competitive position relative to other DCCs, since most parents want to keep their children in the same DCC and not switch when their children reach a new age range. On the other hand, in the absence of competition, a DCC can contract without fear of losing enrollment in its remaining age ranges to DCCs that cover a broader range of ages.

The estimates for local and diffuse disaggregations of overlap density and nonoverlap density in models 3 and 4 are broadly parallel. However, only diffuse nonoverlap density fails to affect the rate of market contraction significantly. Thus the rate of organizational niche contraction was lowered by the presence of DCCs in the same city but in different organizational niches. This suggests the operation of a direct form of mutualism based on complemen-

tary functional differences among DCCs in different organizational niches, for example, infant DCCs generating future demand for toddler DCCs, or DCCs in different organizational niches referring potential customers directly to each other. Separate local and diffuse effects of overlap density suggest that competition among DCCs entailed both geographically localized competition for similar clients and diffuse competition for client-specific resources that are not location-specific. One such resource is financial assistance provided by the Children's Services Division to city residents who qualify for financial assistance, which is budgeted and allocated on the basis of the four age ranges defined in the Day Nurseries Act. Another client-specific resource is skilled labor that is specialized in care for children of particular ages. However, notably, the coefficients for local overlap density and local nonoverlap density are larger than those for their diffuse counterparts. This means that neighboring DCCs generally had larger influences on each other's fates than DCCs operating in different cities. This is consistent with our expectation that interactions among DCCs would be stronger at the local level.

Several of the control variables also influenced rates of DCC organizational niche change significantly. In contrast to earlier studies, the probability of future organizational niche expansion is lowered further by the occurrence of successive organizational niche expansions but increases with the amount of time since the last organizational niche expansion. The probability of future organizational niche contraction is also lowered further by the occurrence of successive organizational niche contractions, but unrelated to the amount of time since the last contraction. By comparison, the likelihood of future expansion and contraction both increase with successive organizational niche changes of the opposing type and decline with the amount of time since the last opposing change. One possible explanation for these effects is the limited number of opportunities available to DCCs for organizational niche expansion and contraction — that is, each organizational niche expansion reduces the options for further expansion and increases options for contractrions, and each contraction has the corresponding opposite effect.

The coefficients for age and size provide little support for structural inertia arguments. Although rates of organizational niche expansion decrease significantly with size, they increase significantly with age, consistent with Singh, Tucker, and Meinhard's (1988) *fluidity of aging* thesis. The rate of organizational niche contraction is unrelated to organizational age but is significantly higher for larger DCCs. Growing DCCs have significantly higher rates of organizational niche expansion and significantly lower rates of organizational niche contraction. DCCs with site-sharing arrangements (SSAs) were more likely to expand their organizational niches and significantly less likely to contract their organizational niches. Nonprofit DCCs were significantly less likely to either expand or contract their organizational niches, possibly because profit fails to motivate nonprofit DCCs to expand into lucrative market segments or withdraw from unprofitable ones.

The coefficients for the age range dummy variables indicate that adding toddler and preschool age ranges increased the rate of further expansion but adding infants lowered the rate. In contrast, dropping any age range increased the future probability of contraction. Notably, these age range effects generally

* $p < .05$

counteract the direct effects of organizational niche changes on the future probability of the same change. For example, while organizational niche contraction lowers the likelihood of future contraction, the significant negative coefficients for the age range dummies means that dropping any age range increases the likelihood. Indeed, the relative sizes of the coefficients indicate that if an initial contraction involved the school-age range, the future rate of contraction actually increased. Estimates for the environmental variables indicate that increases in the Children's Services Division budget increased the rate of organizational niche expansion. In addition, high demand in a DCC's current organizational niche lowered rates of organizational niche expansion and contraction and high demand in other market segments encouraged DCCs to enter them.

Overall, the estimates in Table 3 support our expectations that increases in overlap density would increase the rate of organizational niche expansion but not contraction (hypothesis 1) and that increases in nonoverlap density would lower the rate of both niche expansion and niche contraction (hypothesis 2).

ORGANIZATIONAL NICHE CHANGE AND FAILURE

Table 4 reports maximum-likelihood estimates for the analysis of DCC failure. Models 5 and 6 report baseline models of the effects of organizational niche change on DCC failure that include the effects of overlap density, nonoverlap density, and the organizational and environmental control variables. Model 6 also incorporates geographic distinctions. For convenience, estimates for overlap density, nonoverlap density, and the control variables are reported separately in Appendix E.

Preliminary support for structural inertia arguments (i.e., hypotheses 3, 4, and 5) is mixed. In support of hypothesis 3, the significant and positive estimate for organizational niche contraction and the significant and negative estimate for the organizational niche contraction time-clock indicate that the DCC failure rate jumps immediately after organizational niche contraction and then declines with time after the change. However, the organizational niche expansion and time-clock variables are not significant, failing to support hypothesis 3. Supporting hypothesis 4, the significant positive coefficient for the organizational niche contraction × age interaction means that organizational niche contraction increases the risk of failure with age. Supporting hypothesis 5, the significant negative coefficient for the organizational niche contraction × size interaction means that organizational niche contraction is less hazardous for large DCCs. In contrast to hypotheses 4 and 5, the coefficient for the organizational niche expansion × age interaction is significant and negative and the coefficient for the organizational niche expansion × size interaction is significant and positive. Thus, younger DCCs reap the benefits of organizational niche expansion more slowly and larger DCCs suffer a greater liability from change.

The complex implications of organizational niche contraction for DCC failure are illustrated graphically in Figure 1. The figure compares failure rates for DCCs that contract their organizational niche after one, five, and ten years of operation to failure rates of DCCs that do not make any change.[7] In the figure, a multiplier of greater (less) than 1 indicates that the failure rate is

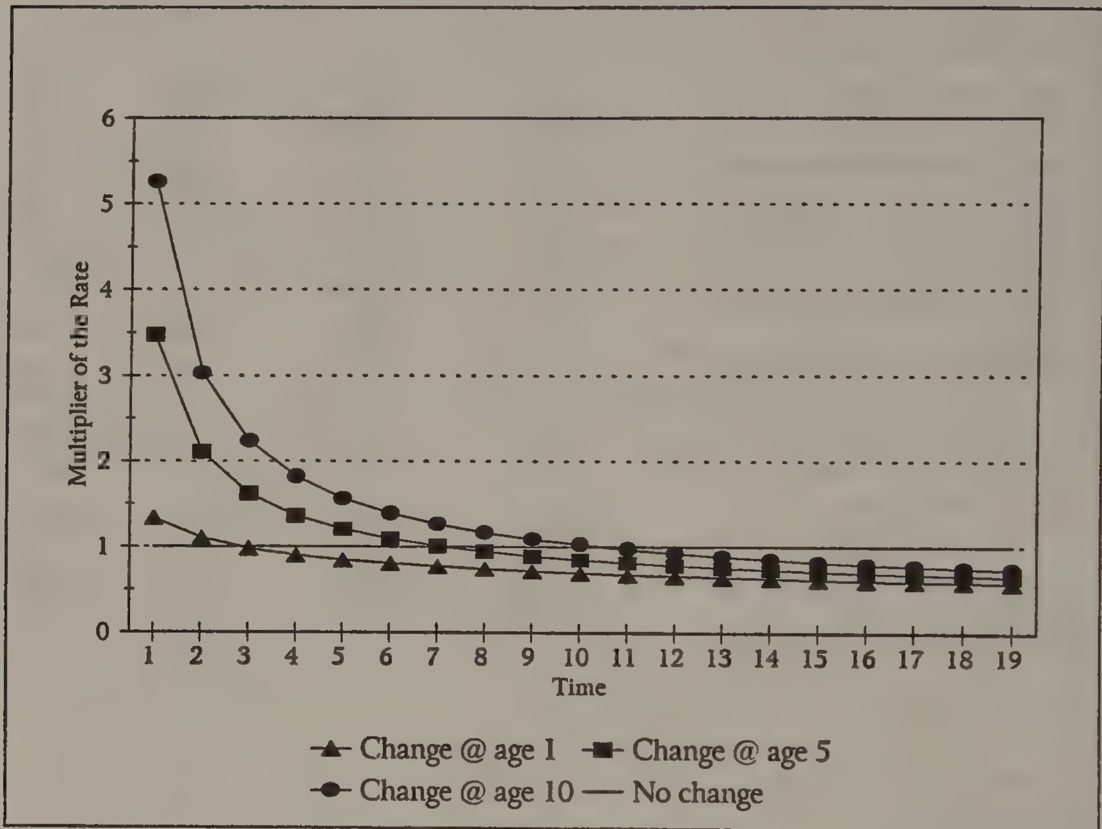
* $p < .05$

increased (decreased) relative to DCCs that have not changed by a factor equal to the multiplier. The multipliers in the figure show that, immediately after a change, failure rates for DCCs that contract organizational niches are up to five times higher than those that do not. The multipliers also show that the size of the initial jump increases with the age at the time of the change. However, the multipliers decline with time after the change and eventually fall below those for DCCs that do not change. A benefit is realized from the contraction after

FIGURE 1: Contraction and Failure

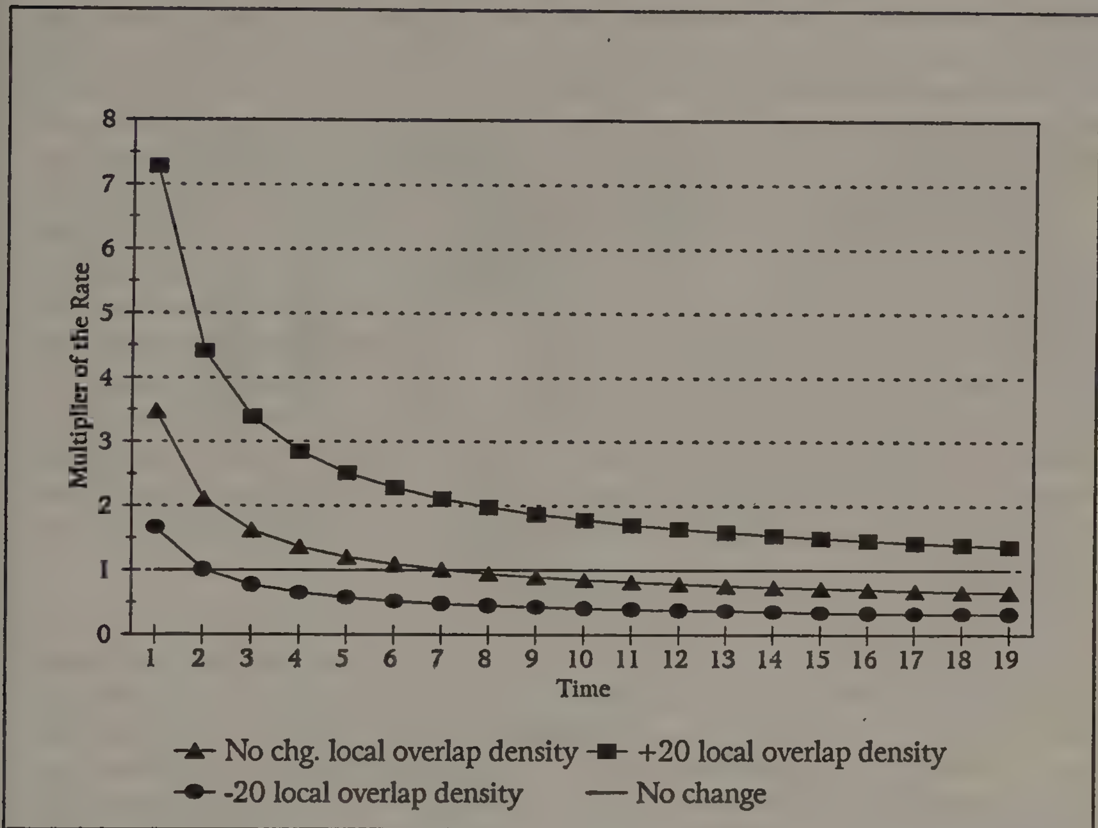


about three years for DCCs making the change at age one, and increases with the age of the DCC at the time of the change.

The effects of organizational niche changes on the intensity of competition are added in models 7 and 8. The significant positive coefficient for Δ overlap density (contraction) in model 7 indicates that organizational niche contractions that raised overlap density caused the failure rate to increase. However, Δ overlap density (expansion) is not significant.[8] In model 8, which incorporates the geographic disaggregation, the coefficients for Δ local overlap density resulting from organizational niche expansion and contraction are both significant and positive.[9] This means that DCCs that reduced competition with nearby DCCs by altering their organizational niches significantly improved their survival chances. Thus, as predicted in hypothesis 5, the survival consequences of organizational niche change depends on its effect on the intensity of competition, although the results are stronger at the constituent city level of analysis.

Combined with the coefficients for the immediate and dynamic effects of organizational niche changes, which remain unchanged in these models, the results indicate that by changing to organizational niches where competition was less intense, DCCs could increase the benefit of organizational niche expansion and moderate the disruptive effect of organizational niche contrac-

FIGURE 2: Contraction and Competition



tion. Figure 2 shows how moving to organizational niches where competition is lower moderates the disruptive effect of organizational niche contraction. This figure compares failure rates for DCCs that contract their organizational niche at age five in ways that leave local overlap density unchanged, increased by 20, and lowered by 20 to failure rates of DCCs that do not make any change. As the figure shows, compared to DCCs whose organizational niche contractions do not change local overlap density, DCCs that lower local overlap density by 20 reduce the magnitude of the initial jump in the failure rate by more than 50% and reduce the waiting time for realizing a survival advantage from seven (Figure 1) to two years. Clearly, DCCs that increase local overlap density by 20 face a quite different fate as a result of their actions.

Several of the control variables also significantly influence DCC failure rates (see Appendix E). While estimates for organizational age are insignificant, the failure rate exhibited negative size dependence. The estimates also indicate that DCCs with POSAs and SSAs and nonprofit DCCs had significantly lower failure rates. The estimates for the environmental control measures indicate that larger Children's Services Division budgets and greater organizational niche demand were associated with significant reductions in the DCC failure rate. The significant negative estimates for the lagged number of failures in the same

organizational niche as a focal DCC support Delacroix and Carroll's (1983) prediction that resources freed up by prior failures enhance the viability of surviving organizations. Finally, increases in overlap density and nonoverlap density respectively raise and lower the failure rate. The effects of local and diffuse overlap and nonoverlap densities are broadly parallel. Again consistent with our expectation that interactions among DCCs would be more intense at the local level, the coefficient estimates for local overlap density and local nonoverlap density are larger than the estimates for their diffuse counterparts.

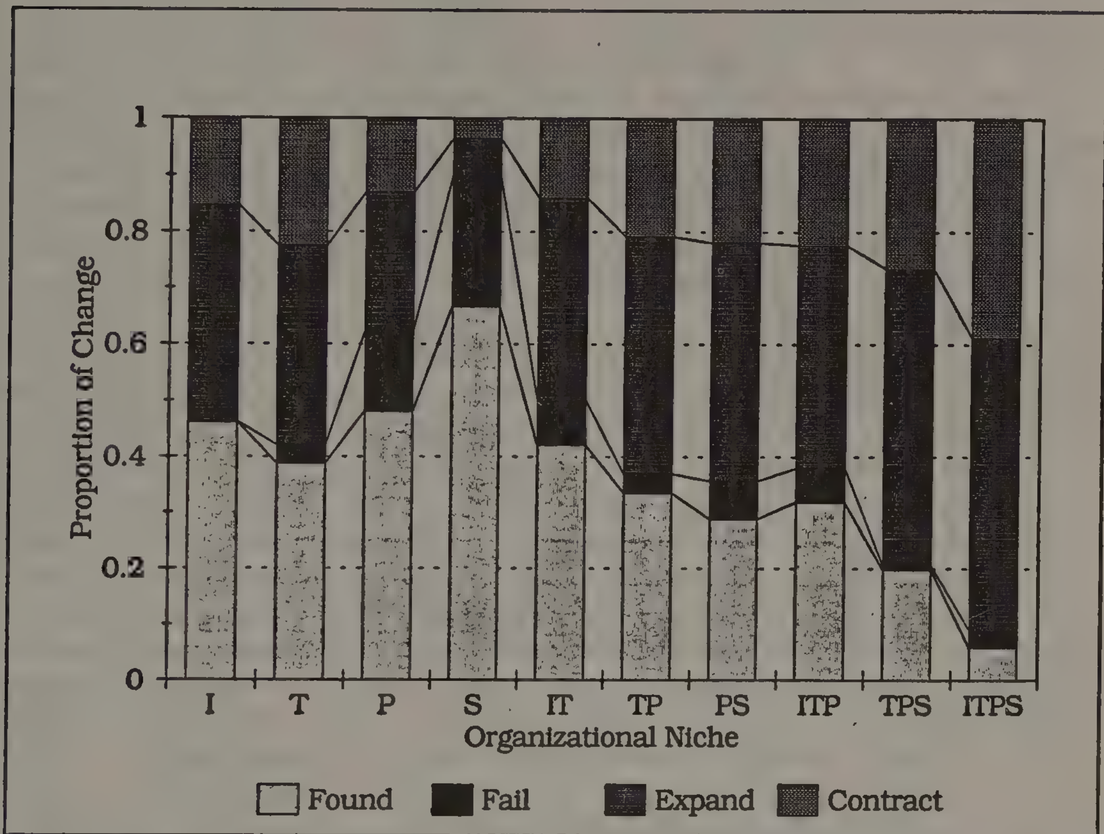
Overall, the estimates for organizational niche contraction in Table 4 support the predictions based on structural inertia theory that organizational niche changes would expose DCCs to an increased failure rate in the short run but that the rate would decline with time (hypothesis 3), and that older and smaller DCCs would be more likely to fail as a result of organizational niche changes (hypotheses 4 and 5). However, the estimates for organizational niche expansion did not support these hypotheses. In addition, the estimates for both niche expansion and niche contraction support our expectation that changes that increase overlap density (i.e., increase the intensity of competition) would increase the failure rate (hypothesis 6) — especially at the local level of analysis.

POPULATION-LEVEL IMPLICATIONS OF CHANGE AND FAILURE

To this point, we have focused on the implications of our analysis for change and failure at the level of individual DCCs. What remains unexplored, however, is how these processes combine to influence the evolution of the DCC population as a whole. To examine this question, we created Figure 3, which shows the contributions of organizational founding and failure and organizational niche expansion and contraction to the evolution of the DCC population between 1971 and 1989. The figure gives the proportions of entries into and exits from each organizational niche during the observation period accounted for by each type of change. For example, in the preschool (P) organizational niche, roughly 50% of all changes were foundings, 20% were organizational niche expansions, and 15% (each) were failures and organizational niche contractions.

Perhaps the most conspicuous feature of the figure is the predominance of foundings over other types of change, reflecting the growth of the DCC population from 1971 to 1989. Organizational niche expansion is the next most prevalent form of change, with organizational niche contraction and failure each providing much smaller contributions to the transformation of the population. It is also apparent that the contributions of the each change to population-level change varies widely — and systematically — across organizational niches. One particularly notable feature of the figure is that proportions of organizational foundings and failures on the one hand, and organizational niche expansions and contractions on the other hand, are each positively correlated with each other ($r = .71$ and $r = .87$, respectively). This implies that processes of transformation and selection tend to predominate in particular segments of the population. In this regard, while the proportions of organizational foundings and failures fall as the number of age ranges in an organizational niche increases ($r = -.87$ and $r = -.42$, respectively), the proportions of organizational niche expansions

FIGURE 3: Population-Level Change



and contractions grow with the number of age ranges ($r = .72$ and $r = .81$, respectively). Thus, in the DCC population, organizational transformation and selection do not characterize different regions of the macro-niche *per se*, but rather, transformation is much more likely to produce change among generalist organizational niches while birth and death are more likely to produce change among specialist organizational niches.

Beyond these relative influences of transformation and selection across the organizational niches making up the population, is it possible to conclude that one process contributes more than the other to the evolution of the population? Three considerations make it difficult to draw such a conclusion. First, although foundings lead numerically, many of these events contributed to the growth of the DCC population rather than to its changing demographic character. Second, because they result in simultaneous changes in two organizational niches, organizational niche expansions and contractions have twice the impact of organizational foundings and failures on population-level change. Third, and finally, because organizational niche changes affect the risk of failure, the combined population-level result is not the simple aggregate of each process separately, and is thus more complex than what is assumed in Figure 3.

Discussion and Conclusions

The purpose of this article was to investigate the roles of adaptation and selection processes in the evolution of organizational populations, a question central to contemporary organization theory. In this research we highlighted interorganizational competition as one primary force shaping patterns of organizational change and survival. The findings extend earlier research on adaptation and selection by (1) demonstrating how competition influences rates of organizational change, (2) showing how the survival consequences of organizational change can depend on its influence on competition, and (3) testing the full structural inertia theory specification of the survival consequences of organizational change.

The results provide evidence that the evolution of the DCC population was shaped jointly by processes of selection and adaptation. In support of the selectionist perspective, the survival prospects of DCCs were subject to the effects of competition and general environmental conditions. Thus, some DCCs responded to competition by dying. In addition, in the case of organizational niche contraction, structural inertia theory predictions about the survival consequences of change were supported fully. And, in the case of organizational niche expansion, although the findings did not support structural inertia theory, younger and larger DCCs still experienced liabilities of change. Lastly, while DCCs did not in general suffer from structural inertia (e.g., rates of change were not generally lower for older and larger DCCs), perhaps as a result of their general smallness and simple structures, DCCs did exhibit several constraints on their capacity for change (e.g., the damping effects of organizational niche expansion on its future probability and the rigidity of market contraction under competitive threat). In support of adaptationist perspectives, however, DCCs demonstrated a capacity to change their organizational niches, often in response to changes in competitive and environmental conditions, and without always jeopardizing their survival, although this was more pronounced in the case of organizational niche expansion than in that of contraction. Moreover, by moving to organizational niches with a lower intensity of local competition, DCCs could improve their survival chances significantly. Together, these findings suggest a complex relationship between adaptation and selection: because the relationship between organizational niche change and failure is moderated by the effects of organizational niche change on the intensity of competition, the population-level result of combined organizational niche change and competitive selection is not the simple aggregate of the separate processes.

Even though DCCs demonstrated a capacity to change organizational niches in ways that improved their survival chances significantly, this does not necessarily imply rational strategic calculation (Swaminathan & Delacroix 1991). The same result can be achieved on a probabilistic basis through random change attempts (March & Olsen 1976). Consequently, we think it is important to pursue further the question of the adaptiveness of DCCs. One way to explore this issue further is to examine whether DCCs moved to organizational niches where competition was, on average, less intense. In fact, the mean change in local overlap density resulting from both organizational niche expansions and contractions is essentially zero (see Appendix D). Thus, DCCs frequently

underwent organizational niche change, often in response to changing competitive conditions, but, on average, the changes DCCs made did not alter the intensity of competition they faced.

One possible interpretation for this absence of systematic effects of organizational niche change on the intensity of competition may be anchored in the bounded rationality of decision makers in organizations (March & Simon 1958). In the case of organizational niche expansion, it seems plausible that decision makers are more knowledgeable about the nature of competition they face in their current organizational niche from past experience than they are about competition in other organizational niches. And expanding their organizational niches would expose DCCs to a different set of competitors. Thus, intentionally rational expansions into new market segments may sometimes have the surprising consequence of exposing the organization to even greater competition, if the new organizational niches are densely populated. Of course, at other times, expansion into new segments may lower competition ex post facto. But, on average, there would be no effect. In the case of organizational niche contraction, since decision makers arguably possess superior knowledge of their current organizational niches, the absence of a systematic effect of organizational niche contraction on overlap density suggests that decision makers may not understand very well the competitive consequences of changing their organizational niches, i.e., that the effects of organizational niche change on the intensity of competition are a joint function of the resulting changes in resource overlap with potential competitors and organizational niche width.

Nevertheless, our results indicate that if DCCs moved to less competitive organizational niches they could improve their survival chances significantly. Thus, in the DCC population, the potential for adaptation, in the sense of improved longevity, is clear. The problem for DCCs is not that adaptive response is impossible or even rare, it is that decision makers are not, on average, able to distinguish between beneficial and detrimental organizational actions. Consequently, while our study provides clear evidence of the adaptive potential of DCCs, it offers little systematic support for a belief in the fundamental adaptability of organizations. Why isn't change more adaptive in the DCC population? One plausible explanation is that DCCs are incredibly nonbureaucratic organizations. This can be viewed as both an advantage (change is relatively easy), and a disadvantage (the ability to collect information on the environment is weak). The combination of reduced information gathering ability with a relatively organic organizational structure could account for our findings — a good deal of change, but not systematically effective change. Contained in this interpretation is a paradox: Organizations that can collect a lot of information often have organizational structures that are difficult to change, while those that can change the fastest often have trouble collecting relevant information to guide changes. Thus, although the organizational simplicity of DCCs might lead one to expect them to possess a high potential for developing *adaptive* responses to competition, in fact, it may lead them only to be responsive.[10] In this regard, it is interesting to note that the findings of this study broadly parallel those of Delacroix and Swaminathan's (1991) study of change among California wineries, a very different setting, but similarly unbureaucratic organizations. More generally, whether changes in response to environments

have adaptive consequences may depend upon the nature of learning processes in organizations (Levinthal 1991).

Several implications and directions for future research follow from this study. First, replications examining our hypotheses regarding competition and organizational change in other populations and for other kinds of changes are needed. Such replications would help clarify the role of organizational change in shaping population dynamics and help establish the generalizability and broader significance of the adaptive effects of competition-reducing changes for understanding the evolution of organizational populations. Implicit in this suggestion is the possibility that the dynamics of population-level change may be population-specific. Population-level change can occur through different rates of founding, failure, and change, and it may be that the prominence of these three mechanisms varies by population. Consequently, this study's results may be peculiar to the changes studied and, as implied above, the DCC population itself, which exists in a highly institutionalized context and comprises small organizations with ambiguous technologies. Future research aimed at identifying factors influencing the adaptiveness of change (e.g., information-gathering ability) may shed light on this question.

Second, distinguishing organizational niche changes by their effect on competition revealed hidden effects of these changes on failure. This may help account for earlier mixed results in studies examining the adaptive consequences of organizational change. In prior research, all instances of a particular kind of change were considered equivalent. While this may provide a reasonable approximation for some kinds of change (e.g., changes that have only intra-organizational implications), the findings of this study suggest that future research on the adaptiveness of organizational change needs to carefully consider the effect of changes on the intensity of competition. Third, our research highlights the importance of including both successful and unsuccessful organizations in studies of organizational change to avoid sample selection bias (Berk 1983; Heckman 1979). If we had studied only surviving firms, our conclusions about the effects of organizational change on performance would certainly have been quite different. For example, since DCCs that move to organizational niches where competition is less intense increase their survival chances, DCCs that move to organizational niches with lower competition are more likely to be survivors. Consequently, if we study only survivors, naturally changes will appear adaptive.

Fourth, in earlier research (Baum & Singh 1994a, 1994b) we studied the effects of overlap and nonoverlap densities on organizational founding and failure in the DCC population. This study extends the scope of our earlier work by examining the interrelated dynamics of overlap density, organizational change, and organizational failure. The results of all three studies support the characterization of interorganizational competition and mutualism implemented here, demonstrating the usefulness of examining the organizational niches of a population's members for understanding the dynamics of organizational populations. At the broadest level, we think the results of this study underscore the utility of examining how intrapopulation processes of competition and mutualism on the one hand, and selection and adaptation on the other hand, interweave to shape organizational evolution.

Notes

1. A counterintuitive though crucial point is that organizational niche expansions (contractions) do not necessarily lead to increases (decreases) in overlap density. This is because the effects of organizational niche changes on overlap density are a joint function of changes in organizational niche width and resource overlaps with potential competitors. We discuss this in detail below.

2. Appendix A shows the range of ages of children, in months, that can be enrolled by DCCs in each organizational niche and the matrix of overlaps among them (i.e., the portion of the client resource space that DCCs in the organizational niches occupy jointly).

3. For example, to qualify for a license to serve ten infants, in addition to planning and implementing activity and nutrition programs geared to the developmental needs of the children, a DCC must provide, among other things, three qualified staff members (i.e., diploma in early childhood education from a recognized institution), one separate activity space and one sleeping area that is separated from any other activity space, ten cradles or cribs and bedding, one table or counter space adjacent to a sink suitable for dressing or changing diapers, one flush toilet or hospital service sink, and 600 square feet of outdoor play space adjacent to the premises and fenced to a minimum height of four feet (Ontario Ministry of Community and Social Services 1988).

4. Metropolitan Toronto contains six cities: East York, Etobicoke, North York, Scarborough, Toronto, and York.

5. Appendix D present means, standard deviations, and bivariate correlations for all independent variables at metropolitan Toronto and local city levels of analysis, respectively. Although the correlations are generally significant, multicollinearity does not appear to be a problem.

6. While yearly data on working women and single parents were not available for every constituent city, census data (Social Planning Council of Metropolitan Toronto 1981) indicate that variation within metropolitan Toronto was not large. In 1981 the percentage of single-parent families with children from birth to five years of age ranged from 9.8 to 13.1%. In the same year, the percentage of women working full-time ranged from 58.1 to 61.5%.

7. Figure 1 is based on coefficients in model 6. The implications are not changed substantively in later models.

8. Although model 7 does not provide a significant improvement over model 5 ($\Delta\chi^2 = 4.71$, 2 df, n.s.), a reduced version of model 7 in which Δ overlap density (expansion) is removed provides a significant improvement ($\Delta\chi^2 = 4.22$, 1 df, $p < .05$) and the estimate for Δ overlap density (contraction) is not changed substantively.

9. Although model 8 does not provide a significant improvement over model 6 ($\Delta\chi^2 = 6.92$, 4 df, n.s.), a reduced version of model 8 in which Δ diffuse overlap density (expansion) and Δ diffuse overlap density (contraction) are removed provides a significant improvement ($\Delta\chi^2 = 6.48$, 2 df, $p < .05$) and the estimates for Δ local overlap density (expansion) and Δ local overlap density (contraction) are not changed substantively.

10. We are grateful to an anonymous reviewer for pointing this paradox out to us.

APPENDIX A: DCC Organizational Niche Resource Base Widths and Overlaps[a]

Org. Niche[b]	Organizational Niche[b] I	T	P	S	IT	TP	PS	ITP	TPS	ITPS
I	18									
T	0	12								
P	0	0	30							
S	0	0	0	60						
IT	18	12	0	0	30					
TP	0	12	30	0	12	42				
PS	0	0	30	60	0	30	90			
ITP	18	12	30	0	30	42	30	60		
TPS	0	12	30	60	12	42	90	42	102	
ITPS	18	12	30	60	30	42	90	60	102	120

[a] (1) The width (in months) of each age range is given on the diagonal;
(2) The overlaps (in months) between age ranges are reported below the diagonal;
(3) Only observed configurations of licensed age ranges are included;
(4) The widths (in months) of the age ranges are used to compute the raw resource overlaps, since the distribution of resources (i.e., children in Metropolitan Toronto) across the age ranges is roughly equal to the widths of the age ranges.

[b] Organizational niches:

I = Infant, 0-18 months
T = Toddler, 19-30 months
P = Preschool, 31-60 months
S = School-age, 61-120 months
IT = 0-30 months
TP = 19-60 months
PS = 31-120 months
ITP = 0-60 months
TPS = 19-120 months
ITPS = 0-120 months.

APPENDIX B: Resource Overlap Weights by Organizational Niche[a]

Org. Niche j[b]	Organizational Niche i[b] I	T	P	S	IT	TP	PS	ITP	TPS	ITPS
I	1	0	0	0	600	0	0	.300	0	.150
T	0	1	0	0	.400	.285	0	.200	.117	.100
P	0	0	1	0	0	.714	.333	.500	.294	.250
S	0	0	0	1	0	0	.667	0	.588	.500
IT	1	1	0	0	1	.285	0	.500	.117	.250
TP	0	1	1	0	.400	1	.333	.700	.411	.350
PS	0	0	1	1	0	.714	1	.500	.882	.750
ITP	1	1	1	0	1	1	.333	1	.411	.500
TPS	0	1	1	1	.400	1	1	.700	1	.850
ITPS	1	1	1	1	1	1	1	1	1	1

[a] The resource overlap weights w_{ij} in the table are the ratio of the overlaps between organizational niches i and j and the width of resource base of i. The values for the overlaps and widths are given in Table 1.

[b] See notes to Appendix C.

APPENDIX C: Overlap Densities by Organizational Niche, 1971-89[a]

Year	Organizational Niche[b] I	T	P	S	IT	TP	PS	ITP	TPS	ITPS
1971	9	14	104	58	10	77	73	57	66	57
1972	14	20	110	61	14	83	77	62	70	61
1973	21	26	120	70	21	91	86	70	79	70
1974	27	24	137	77	27	105	96	82	88	79
1975	33	36	164	78	34	127	106	99	98	88
1976	36	40	197	109	37	152	138	117	126	113
1977	36	37	214	120	36	163	151	125	137	122
1978	39	40	222	120	41	171	153	131	140	125
1979	33	45	238	142	37	182	173	137	158	139
1980	35	51	257	163	41	197	194	149	177	156
1981	33	53	268	177	41	206	207	154	189	165
1982	37	62	301	198	47	232	232	174	212	186
1983	41	72	319	211	53	247	246	185	226	198
1984	43	85	339	221	59	265	260	199	239	210
1985	53	120	370	234	78	297	279	224	259	229
1986	67	151	415	264	99	338	314	257	294	260

The Settlement Experience of Latinos in Chicago: Segregation, Speculation, and the Ecology Model

JOHN J. BETANCUR, *University of Illinois at Chicago*

Abstract

This article describes the process and characteristics of Latino settlement in Chicago. It identifies elements of segregation and discrimination associated with Latino status. The analysis disagrees with Massey's claim that Latino settlement is proceeding along the lines of the ecological model. It claims that, though descriptively relevant, the model is not very useful for explaining *the Latino experience, particularly prejudices and practices related to the status of Latinos as a dominated group in the U.S. The author claims that a combined historical, qualitative, and quantitative analysis reveals crucial qualifications that statistical analyses often miss.*

This article addresses Latino settlement in Chicago. It contends that this experience has been characterized by residential exclusion and speculation rather than by opportunity and mobility. The analysis disagrees with descriptions of Latino settlement based on the ecology model (Aguirre, Schwirian & LaGreca 1980; Massey 1987). It claims that the model, though descriptively relevant, is not very useful for *explaining* the Latino experience. The argument is specifically different from Massey's (1987) version, which contends that while the ecological model cannot explain black residential distribution, it is valid for Latinos. Statistical evidence may suggest the relevance of aspects of the model, but it misses key qualifications and elements suggested here.

The argument is constructed in four sections. The first argues that Latino immigration reflected U.S. domination of Latin America. The second examines ways in which the resulting vulnerability and status of Latinos allowed for real-estate speculation to exploit their quasi-racial status and highlights the resulting processes of residential exclusion. The third describes the settlement patterns of Latinos today and brings up additional evidence questioning the applicability of the ecological model to them. It concludes with a brief discussion of findings.

 Social Forces, June 1996, 74(4):1299-1324

The Ecological Model

The ecological model either in the original form or in later versions has dominated analyses of residential segregation. The initial version explained urban change in terms of competition and succession among land uses. In residential areas, one ethnic group succeeded another one when the latter left. Alternatively, groups engaged in competition and displaced each other. Underlying this process was the assumption of mobility: as groups improved economically, they moved into better areas. Neighborhood change was, then, explained in terms of invasion, succession, and mobility (Park & Burgess 1921; Park, Burgess & McKenzie 1925). A more recent version of the ecological model, *social area analysis,* views residential differentiation as reflecting the increasing complexity associated with development. As development produces different groups, people of similar backgrounds seek to live with their kind and the result is social separation and segregation (Berry & Horton 1970; Berry & Kasarda 1977; Shevky & Bell 1955).

Along these lines, Massey (1987) proposed an updated version. In his view, ethnic segregation stems from "the interplay of the opposing forces of concentration and dispersion" (317). Concentration results from increasing spatial differentiation; dispersion, from mobility and acculturation. Immigration is a case in point. Immigrants hold low-wage jobs and need to minimize costs. Migration chains lead them to low-rental ethnic areas, near work, relatives, and friends. If differences with current residents are too deep, a process of replacement follows. When they "reach a threshold of density" (318), they develop their own social infrastructure, their enclaves become the basis for solidarity, and more members join the group (concentration). As they acquire the language, culture, and values of the host society, they get better jobs and disperse into higher-income native areas with better services. Since, by that time, they have developed the values and status as natives, their move is not likely to produce a new process of replacement and succession but one of integration and assimilation.

Massey's (1987) update provides a version that is more flexible, while getting rid of outdated elements ("a rigid biological analogy and a sentimental, ethnocentric view of ethnicity now discredited") and introducing others left out by previous formulations ("larger processes of social change and economic development"). He removes one of the most controversial applications of the model by leaving blacks out of the equation. Studies of segregation, he claims, "suggest that black segregation stems more from white prejudice than from the socioeconomic processes specified by the ecological model" (316). Meanwhile, he includes Latinos as "ethnics" properly represented by the model (326-28). This decision, we argue, misses the significance of the Latino status. Not only have Latinos been discriminated against because they are Latino, but discrimination has been reflected in unique forms of manipulation and exploitation affecting their settlement and mobility in ways that differ significantly from those of European immigrants.[1] Thus, while the literature refers to Latinos as ethnic, national, or racial groups, often without much attention to the implications of the chosen term, this article argues for the need to construct the term historical-

ly. For this, the article engages in analysis that emphasizes the common bonding of subjugation of Latinos in the U.S. and its specific residential manifestations. The terms *racialization* and *race*, for instance, are used to highlight the application of prejudice and discriminatory practices in the housing market to them because they are Latino. Generally, however, the article uses the term *Latino* within the context of domination established in the next section.

Latino Importation or the Production of a New Urban Minority

The migration of Latinos to the U.S. and Chicago has been closely associated with economic exploitation and political domination of Latin America by the U.S. (Bach 1978; Betancur, Córdova & Torres 1993; Bonilla & Campos 1981; Centro de Estudios Puertorriqueños 1979; Fernández Kelly 1983; Portes and Walton 1981; Sassen 1988; Teitelbaum 1985).[2] Along these lines, the experience of Latinos has been characterized by extreme forms of domination and exclusion because they are Latino (Acuña 1988; Pachón 1985; Padilla 1987). Employer abuses, labor segmentation and immobility, and segregation are clear manifestations of this (Barrera 1979; Blauner 1969; Bullock & Manus 1990; Lane & Escobar 1987; Meléndez 1988; Omi & Winant 1986; Padilla 1987; Reisler 1976; Taylor 1932; Yinger 1985).

The presence of Latinos in the U.S. is largely the result of forceful annexation or purchase of Latin American territory and people by the U.S. (northern Mexico, Puerto Rico); use of migration as an escape valve for explosive social conditions (Puerto Rico, Central America); a strategy of the cold war (Cuba, Nicaragua, Dominican Republic); distortions related to U.S. investment in Latin America (Sassen 1988); or a convenient, temporary solution to so-called labor shortages (Kirstein 1977). These actions have followed from U.S. claims on the region as its sphere of influence.[3]

Northern Mexico became part of the U.S. through conquest and purchase (1848). This is also true for Puerto Rico as a result of the U.S.-Spain colonial war of 1898. Migration to the U.S. resulted from the ensuing transformation of the island by U.S. interests (Sanchez-Korrol 1983). Dependent development in Mexico led to massive displacement of peasants who were then imported by U.S. employers and turned into a dominated segment of disposable, cheap labor. Not only were they admitted under special arrangements (e.g., the Bracero Program of 1942-64 and the Temporary Admissions Program of World War I), but employers and government colluded to generate a stream of undocumented and unprotected workers (Corwin 1978; Kirstein 1977; Kiser & Kiser 1979).

A steady and large flow of Mexicans to Chicago resulted from their *importation* by railroad, steel, and other industries,[4] as part of the industries' strategies of labor control (Año Nuevo Kerr 1976; Taylor 1932). These industries systematically subjected Mexicans to labor segmentation (Año Nuevo Kerr 1976; Lane & Escobar 1987; Taylor 1932). Large imports of temporary Mexican workers to Chicago and the Midwest took place in the periods 1916-28 and 1942-64. Many remained or came back as undocumented workers. Their

importation encouraged others to follow and became the basis for chain and circular migration ever since.[5]

Mexicans have been employed and laid off at convenience, imported, deported, and prevented from competing for better jobs.[6] The nativist debate of the 1920s portraying them as "perhaps the worst element that comes into the U.S.," "serf, peon and slave types," "undesirable people," and "inassimilable manpower" (Reisler 1976:200-205); the bitter repatriation drives of the 1921 and 1929 depressions; and the 1954 "wetback" and later operations of massive deportation speak to this. They testify to the framing of Mexicans as a cultural and racial threat, the justification of their use for unskilled physical work, and the claim that they were not worthy of full participation in U.S. society (Reisler 1976). Scapegoating of Mexicans has continued through the years.[7]

Most recently, they are being lured into Chicago by minimum-wage jobs in sweatshop manufacturing and services. Employers in need of unskilled workers depend largely on them. As a result of the terms of migration, the types of workers recruited, the jobs open to them, and chains tying previous entrants to new entrants, their immigration has been highly selective of poor, unskilled, uneducated Mexicans. These factors have led them to industries and occupations similar to those of their ancestors. The conditions and selectivity of their immigration led to communities with very little Mexican leadership or professional cadres.

The immigration of a large group of Puerto Ricans[8] to Chicago started with importation of contract labor for service, farm, and manufacturing work after World War II, with the cooperation of authorities at both ends.[9] These recruits became the nuclei and the impetus for further recruitment and chain migration. Workers were imported by employers unable to secure U.S. labor under the conditions and at the wages offered (Maldonado 1987; Padilla 1947). Once in Chicago, they faced highly exploitative conditions — wages below those prevailing for similar work; transfers without notice; long hours; deduction of recruiter fees and transportation costs from their paychecks; poor housing and lodging (Martínez 1989; Padilla 1947). Even though Puerto Ricans are U.S. citizens, the terms and conditions of their importation and employment have been close to those of Mexicans. They have been categorized and treated as blacks (Padilla 1987). Unlike European ethnics, the terms of their importation produced a largely single-class group without the cadres required for the development of healthy communities.

Today, after more than a century in the U.S., the white-Latino gap has not improved (Bean & Tienda 1987; Morales & Bonilla 1993). Though equal to whites in the eyes of the law, Latinos have been consistently unequal politically and socioeconomically (Hero 1992). As Barrera (1979) argues, their condition has been shaped through a combination of conquest, arranged immigration,[10] and other forms of domination amounting to internal colonization. Studies of both groups in the U.S. describe their experience as one of political domination and economic exploitation (Acuña 1988; García 1988; Jennings & Rivera 1984; Sánchez-Korrol 1983). In Chicago, the income and occupational gap between Latinos and whites has been increasing (Betancur, Córdova & Torres 1993).

Hence, Mexicans and Puerto Ricans came into the U.S. under conditions that were essentially different from those of Europeans on whom the ecology

model is based. Most Europeans did not undergo this process of manipulation and domination, received a permanent migrant status from the beginning, and were extended the opportunities of earlier white immigrants. In contrast, Latinos were shaped into an internally dominated labor segment, second-class citizens, indeed, a minority group largely along the lines of blacks. This condition has been reproduced over the years.

The Formation of Segregated Latino Areas

In Chicago, Mexicans were initially housed in bunkhouses or railroad camps or were directed to boarding houses by the companies (Taylor 1932).[11] This housing was generally temporary — as their job assignments were meant to be. With increases in their numbers and extension of their stay, they sought housing near the plants. Meanwhile, used to exploiting ethnic feelings, slumlords found a new source of profit — Mexican origin — among the newcomers.

The landmark research of Taylor, Abbott, Hughes, Constable, Jones, Britton, and Redfield is extremely valuable here. According to them, landlords rented to Mexicans vacant, unhealthy, run-down property in pockets of deterioration where Europeans would not live (Hughes 1925, 1937; Jones [1928] 1971; Redfield 1924-25; Taylor 1932). They ended up in back parts, rear houses, and basements (Briton & Constable quoted by Taylor 1932). Restriction to the poorest areas "largely among Negroes" (224), produced clusters of artificial scarcity that allowed landlords to charge Mexicans — and blacks — higher rents than they charged any other groups.

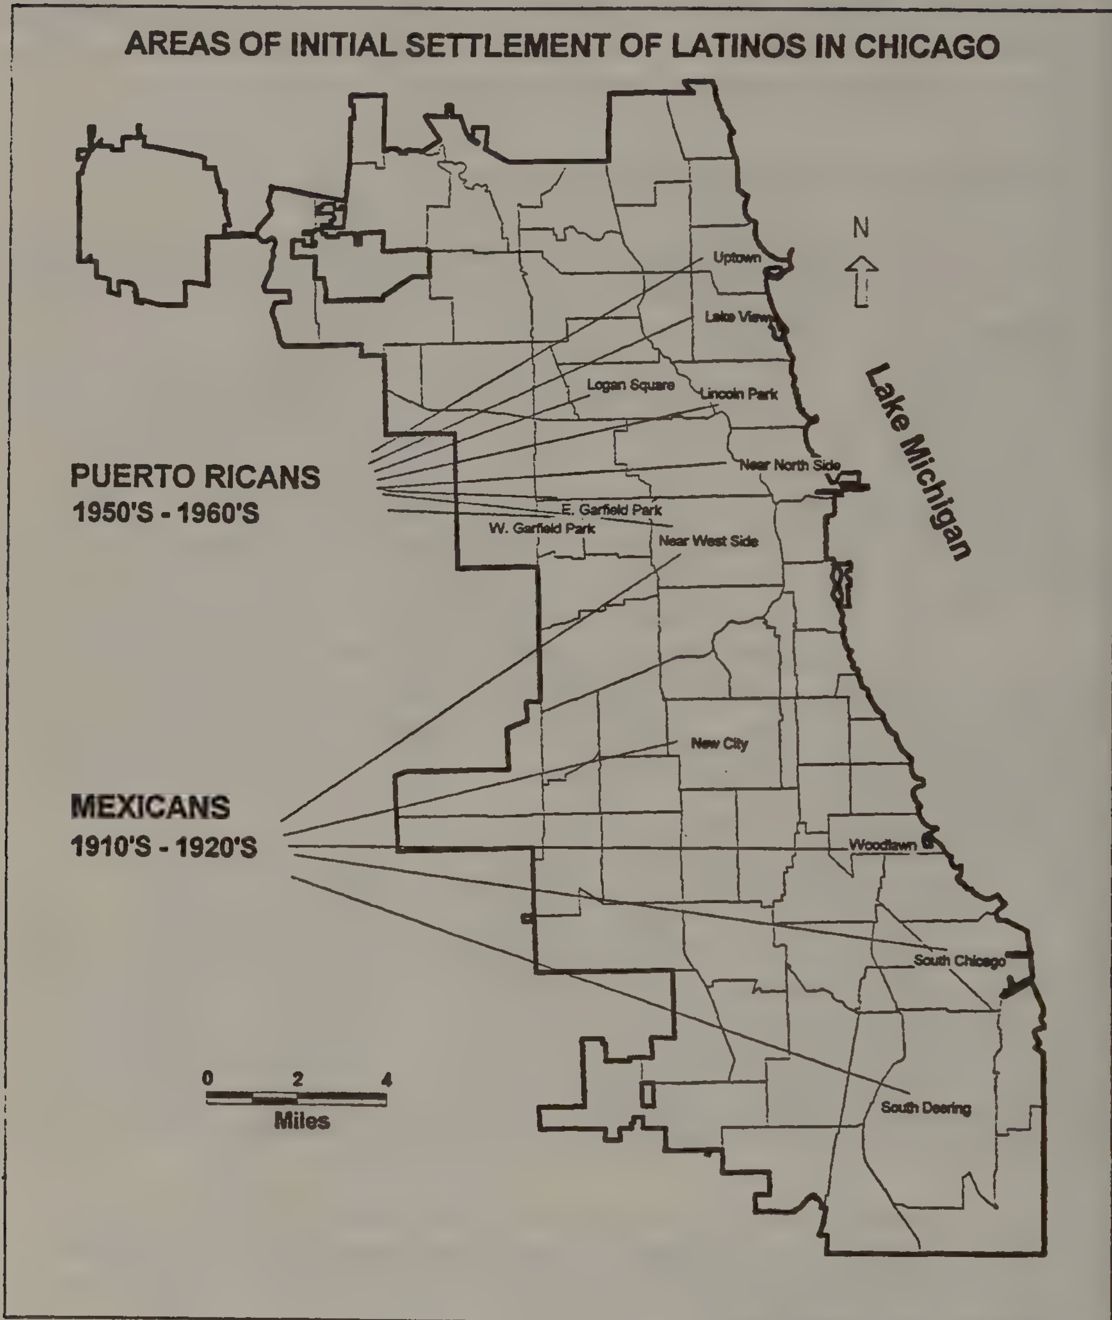
Taylor (1932) reports that while peer pressures forced landlords to exclude Mexicans from European ethnic — particularly resident homeowner — areas, profit interests motivated them to rent to Mexicans. Some dispersal to the fringes resulted from this. Meanwhile, opposition to Mexicans had a strong racial basis. Explanations about this rejection ranged from behavioral and cultural traits to color and national origin. Real-estate businesses claimed that Mexicans had a negative impact on property values. This is a clearly racist factor: as Mexicans move into an area, whites no longer want to live there. Property values depreciate as a result.[12] However, the industry managed to make up for this:

> Since the Mexicans have come in, the real estate values have declined to almost nothing. But the rental value of the buildings goes up $10 to $15 per flat; the Mexicans can only get in a very few places, and they have to pay what is asked (a realtor quoted by Redfield in Taylor 1932:222n)

Ethnic restrictions succeeded in clustering Mexicans in their own spaces (Taylor 1932). Latino origin facilitated this. The first Latino clusters were located in South Chicago-South Deering (next to the steel mills), the Hull House area (near the railroads and other central sources of employment), and in Back of the Yards (close to meatpacking houses; see Figure 1).

Available evidence suggests that clustering and speculation have been a constant for Latinos up to today. Analysis of the period 1930-70 points to the persistence and firm rooting of the initial Mexican clusters and the economic

FIGURE 1: Areas of Initial Settlement of Latinos in Chicago



position of Latinos vis-à-vis other groups (Año Nuevo Kerr 1976:12). Some dispersal was forced by fear of recognition and deportation in the 1930s; yet "continued residential restriction led to immobility" (95). A 1935 survey of persons on relief concluded that racial prejudice, segregation, labor segmentation, and cultural distinctiveness plagued the Mexican population in Chicago (Hughes 1937). As a result, through the 1930s, Mexicans "experienced greater economic difficulties than any other ethnic groups in the city, except Blacks" (Año Nuevo Kerr 1976:82).

Conditions did not improve in the 1940s. The 1948 Report of the Mexican Sub-Committee of the Metropolitan Welfare Council (Pax 1948) indicated that segregation and isolation in the three initial clusters, discrimination, and poverty prevented the advance of the group. Moreover, new immigrants continued to settle in or around the clusters (Año Nuevo Kerr 1976). Evidence also points to residential mixing among Mexicans of different social statuses, educational levels, and generations from the early 1920s to the 1970s (Año Nuevo Kerr 1976).

In the 1950s, highway construction displaced many from the eastern and northern borders of the Hull House area. In the 1960s, most of the area was cleared for a university campus, forcing residents to relocate. Displaced Mexicans joined a new cluster that had been forming out of the Hull House Mexican cluster,[13] to the south. More deteriorated than the previous one, this area — Lower West Side or Pilsen — soon became the first *majority* Mexican and Latino community in Chicago[14] and the basis for organization of the group. Latino population also increased steadily in the other clusters after the 1960s (Latino Institute 1983). Along with population increases came public neglect, slumlordism, and disinvestment. Negligible levels of Latino homeownership, overcrowding, arson, neglect, and high rents have characterized these areas in the last decades (Chicago Fact Book Consortium 1984).

Puerto Ricans also settled in small clusters according to their place of employment and the original housing provided by recruiters. They were first placed in cheap hotels, old passenger coaches, public housing, and similar housing. They then pushed their way into single-room-occupancy units and boardinghouses, shared quarters, and other run-down or vacant rental properties nearby. They gave a new lease on life to substandard housing. Initial clusters were located on the Near North Side and in Lincoln Park, Uptown, and Woodlawn (Martínez 1989; Padilla 1947; see Figure 1). Other groups settled later on the Near West Side; in West and East Garfield Park; and in Logan Square and along Division Street on the Near Northwest Side (Padilla 1987; see Figure 1). They were allowed in these areas because of vacancies generated by disinvestment and suburbanization. Blacks were also entering East and West Garfield Park and Woodlawn in large numbers at the time.

Like Mexicans, Puerto Ricans moved into rental housing in the most highly disinvested sections of those areas. Their stay in most of them was short. Highway construction and urban renewal displaced them in succession from the Near West and Near North sides and Lincoln Park (Jiménez 1974; Padilla 1987). Outnumbered by blacks, they also had to leave Woodlawn and East and West Garfield Park[15] (Padilla 1987). Puerto Ricans, then, consolidated along Division Street, in the West Town and Humboldt Park communities.[16] Unable to secure

white tenants, landlords reluctantly rented to them. Their conditions allowed very few to purchase. Owners, then, turned many units into rooming houses, kitchenettes, and other, often illegal, conversions for rent. Landlords speculated with the level of need and rejection of Puerto Ricans by limiting their choices through clustering and overcrowding in small, substandard, and unhealthy places with practically no maintenance or housing code compliance (Padilla 1987).

Discriminated against and displaced from their initial clusters, Puerto Ricans saw their move into the Division Street area as an opportunity to form a community they could call home away from home (Padilla 1987), one, indeed, from which they could not be so easily displaced. This became, then, the residence for Puerto Ricans of different occupations and economic and social status, with various generations living together. As in the case of Mexicans, Puerto Ricans faced housing discrimination from the beginning (Padilla 1987). Not only were they limited to clusters but "were forced to pay higher rents in those buildings that were open to them" (117). They suffered repeatedly from arson when landlords tried to recover their investment from insurance companies. One-third of the local housing was destroyed by abandonment, demolition, and fires between 1970 and 1978 (Padilla 1987).

Today, gentrification is forcing them out, into less accessible areas of recent disinvestment and "white flight" to the west and north.[17] Higher-income groups — whites mostly — have been incrementally replacing Latinos who can no longer afford the gentrifying neighborhood.[18] Meanwhile, Latinos are moving into adjacent areas of disinvestment that had become less desirable from their closeness to Latino concentrations and to white flight.

In short, the experience of Puerto Ricans has been one of clustering, displacement, and reconcentration. Also, Mexicans expanded out of their initial clusters or were displaced to reconcentrate nearby. Both were forced into this by the combined forces of real-estate speculation — illustrated here — and racism rather than as a result of upward mobility or integration. Mobility was largely horizontal. Forced and continuous moves also made many of them live in permanent transition. They have not displaced other ethnics. Latino-related speculation has been dictating the terms, rather than assimilation, choice, competition, and mobility. Latino solidarity has been maintained, indeed reinforced, by exclusion, segregation, and discrimination (Padilla 1987). In spite of some dispersal present since the beginning but largely restricted to the fringes of Latino concentrations (Taylor 1932 and our own research), movement out of these clusters has never had the massive character of European ethnic groups' dispersal.

From Arranged Immigration to Housing Discrimination and Segregation

The previous analysis has linked labor segmentation and residential clustering to the condition of being Latino. The present section summarizes other activities of the real-estate industry exemplifying this and further establishing its relationship with Latino settlement patterns. In particular, it agrees with the

claim that Latinos became a quasi-racial segment within a dual residential market system (Bradford 1991; Dennis & Pottinger 1988).

As early as 1933, in his ranking of groups by their impact on property values from positive to negative, Hoyt (1933) placed Mexicans last, behind blacks. The negative impact of these two groups on property values has always been assumed in real-estate theory and practice. This assumption has its roots in racism as the presence of these groups makes an area undesirable or less desirable for whites. It, in fact, has resulted in the rating of Latino and black areas as highly risky and in the disinvestment associated with such an assessment (Bradford 1991). It has facilitated group-based neighborhood change in Chicago and elsewhere as speculators use these groups to destabilize and turn around white areas (Boyer 1973; Bradford & Rubinowitz 1975; Bradford, Rubinowitz & McGowan 1975; Feins 1976). Finally, it has produced numerous racist schemes including steering, redlining, protective covenants, and segregation.

Before the 1949 Supreme Court decision that made restrictive housing covenants illegal, even public documents stressed separation and protective covenants as a condition for stability in land values (USFHA 1938, 1947). Practices of the industry did not change much after this decision (Berry 1979; Bradford 1991) or after the Fair Housing Act of 1968 (Kushner 1992). This was reflected in FHA maps circling minority areas to indicate that they were excluded from lending (Kushner 1992). Redlining of minority areas of residence in Chicago has been widely documented by the Woodstock Institute and others (Squires, DeWolfe & DeWolfe 1979). Using the data of the Institute, Shlay (1987, 1988) established that the higher the proportion of Latinos and blacks in an area, the lower the number of conventional loans. Steering of minorities to selected areas has been demonstrated in Chicago particularly through Fair Housing Audits (Austin Turner 1992; Galster 1992; Urban Institute 1991). Other mechanisms perpetuating housing discrimination and segregation have been identified in audits and other research in Chicago and elsewhere. They include withdrawal of conventional loans from Latino and black areas paired with the increase and abuse of FHA/VA-insured loans (Boyer 1973; Bradford, Rubinowitz & McGowan 1975; Feins 1976; Peterman & Sanshi 1991); speculative schemes associated with racial change (Boyer 1973; Bradford & Rubinowitz 1975); unequal outcomes in the search for housing compared to whites with the same incomes (Galster 1992); unequal treatment in housing transactions (Austin Turner 1992); failure to serve minorities adequately (Weink 1992); discrimination in terms and conditions for rental housing, sales and marketing of property, and financial assistance for home buyers (Austin Turner 1992); minority purchases with cash or on contract (Bradford 1991); poor law enforcement (Dedman 1988; Kushner 1992); and discrimination in housing availability (Downs 1992).

Wachter and Megboulegbe (1992) relate discrimination against Latinos and blacks in housing to discrimination in labor markets via income. Similarly, Alba and Logan (1993) have established that even in the suburbs blacks and Latinos, in that order, exhibit a great deal of separation from whites. They also concluded that whites with distinguishing characteristics are much more likely to live together than with blacks or Latinos with similar nonethnic characteristics. Studies of segregation have repeatedly demonstrated that blacks and Latinos

have the highest rates of segregation (Massey & Denton 1987). While less segregated than blacks (White 1987), Latinos have consistently undergone extreme segregation in Chicago (Orfield & Gaebler 1991).

Two other factors suggest that the above trends will carry into the future: the first is a behavior-and-expectations mechanism and the second is the increasing subtlety of discriminatory practices. A long history of discrimination and segregation has produced expectations and beliefs that keep groups in their place. Fears are internalized and turned into behavior that perpetuates the status quo. Practices become then "constraints" in the settlement of groups. Second, discrimination and segregation take place today under an appearance of neutrality that the industry has been perfecting over the years. Control of listings, targeted marketing, claims of affordability, minimum loan amounts, higher closing points for smaller loans or risky areas, restrictions on financing of older houses or homes in racially mixed areas, informal covenants, poor enforcement of regulations, restrictions on children, claims that an apartment was just rented or that a house is under contract are good examples of practices often used to disguise discrimination (Austin Turner 1992; Berry 1979; Bradford 1991; Luttrell 1970).

In short, the condition of Latinos has been exploited and perpetuated by the real-estate industry in Chicago and elsewhere. It has been used to destabilize white areas or produce so-called white flight, to extract exorbitant profits from residential change, to create artificial pockets of scarcity by limiting the areas and types of housing available to Latinos, to devalorize areas,[19] and to maintain segregation (Squires et al. 1987; Suttles 1972). These factors, in turn, lead to separation, concentration in areas of disinvestment and white flight, and clustering and reclustering but, very particularly, high levels of manipulation in the residential market.

Recent Settlement Trends and Housing Conditions of Latinos in Chicago

This section completes the story of Latino concentration and segregation in Chicago with the introduction of relevant statistics and other current evidence. It also argues that initial, supposedly temporary situations have become permanent for Latinos in the city. Similarly, it shows that, overall, their housing situation is very similar to that of blacks in the city. This analysis draws on statistics from the U.S. Census of Population and information from other studies. It profits from the author's knowledge of Latino areas in Chicago, from formal and informal field observations over the last fifteen years, and from multiple conversations with persons in the real-estate industry, Latinos, and others.

With the exception of South Chicago, the traditional areas of Mexican and Puerto Rican concentration have increased their Latino population in recent decades (see Table 1).[20] Additional Latino settlement has taken place in the original clusters or has spilled over into their surrounding areas (Figure 2). Latino population increases have often been accompanied by increases of blacks; these, in turn, have led to decreases of Latinos next.[21] The process of disinvestment and white flight slowly opened the West Town, Humboldt Park, and

TABLE 1: Communities of Major Latino Concentration — 1990 Central Indicators[a]

Logan Square areas to blacks.[22] With the exception of the Hull House area, Latino concentrations, thus, expand today out of the original cores established in the 1910s and 1920s by Mexicans and in the 1960s and 1970s by Puerto Ricans (Figure 2 and Table 1). In Pilsen, Mexicans moved southwest into South Lawndale[23] to reach 85% of the area in 1990. They expanded further into the adjacent suburbs of Cicero and Berwyn to the south and west. Latinos have been moving east of South Chicago into the East Side[24] and into the suburbs. Blacks have followed Latinos into the East Side. While no blacks were registered on the East Side by the 1990 census, an increasing number of them has been entering since.

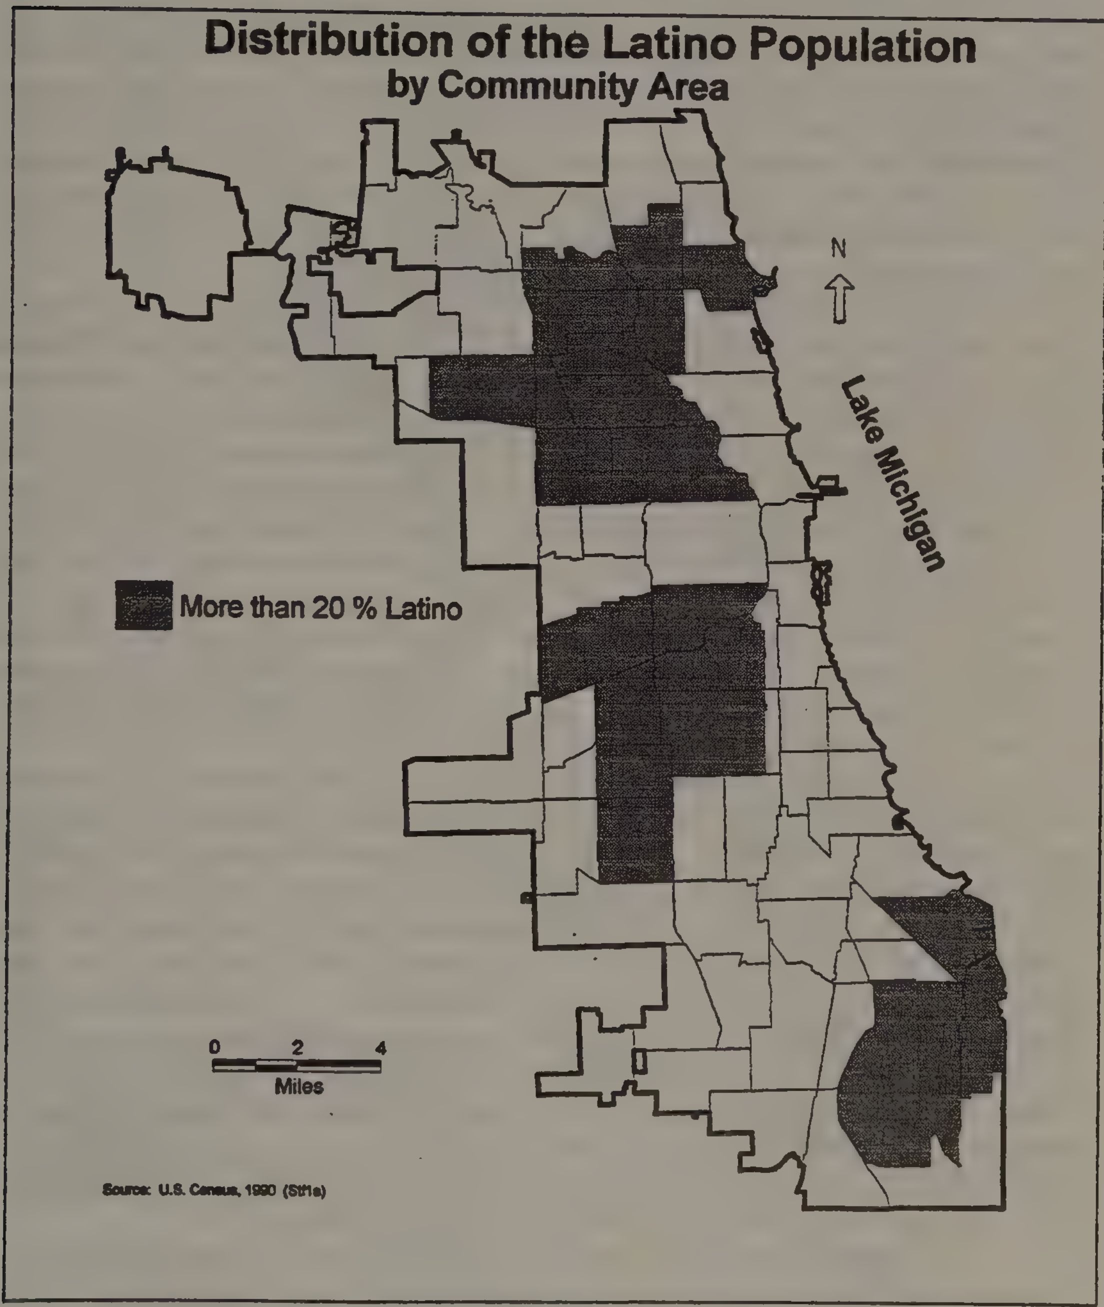
Similarly, Latinos expanded southwest from Back of the Yards into neighboring areas such as Brighton Park, McKinley Park, Bridgeport (with 0% blacks), and Gage Park[25] (1% black in 1980 and 5% in 1990). Not only are Latinos increasing their share in these white areas, but they are forming a buffer zone between whites to the west and blacks to the east. The Division Street core in the near northwest has also been expanding into adjacent areas to the west and to the north including Hermosa, Avondale, Albany Park, North Center, Lincoln Square, Belmont-Cragin, and Irving Park.[26] Expansion has reached into nearby old suburbs such as Addison and Melrose Park. These communities had no or less than 3% blacks in 1990. West Town, Hermosa, and Belmont-Cragin separate the black West Side from white and mixed — white, Latino, and Asian — areas to the north and west. Gentrification in Uptown, Lakeview, and West Town has also pushed many Latinos into these areas.

Other Latinos have been entering Mexican and Puerto Rican areas since the late 1950s. These two groups also lived with each other in South Chicago (with the recruitment of Puerto Ricans for work in the steel mills after World War II) and in West Town (where Mexicans started moving in such numbers since the 1960s that, by 1990, they had surpassed Puerto Ricans). Even though areas such as the near southwest and sections of the near northwest are identified as Mexican and Puerto Rican respectively, Latino neighborhoods are becoming increasingly mixed, sharing experiences and problems with nationals from other Latin American countries.

As mentioned before, some areas have been losing Latinos to gentrification[27] since the 1970s, but particularly in the 1980s and 1990s. Such is the case of the east end of Pilsen, which has gained whites while losing Latinos. Latino clusters are near extinction in gentrified Lakeview — adjacent to Lincoln Park — particularly in the middle of the community. In West Town, gentrification has been advancing steadily in Wicker Park, Bucktown, and the southeast sections with substantial reductions of Latinos. Similar displacements have been taking place in Logan Square and Uptown.

Currently, 83% of Latinos are concentrated in three main contiguous areas, namely the near to mid northwest, the near to mid southwest, and the far southeast (see Figure 2). The northwest area includes 11 communities with populations that are 20% or more Latino — Latinos are 20% of the population of Chicago — which comprise 45.1% of the city's Latino population. The southwest area includes 8 communities and comprises 33% of the Latinos in Chicago. And the far southeast includes 3 communities with 5% of the city's Latinos. Added to these is an area in the far north end, Rogers Park, with 2.2%,

FIGURE 2: Distribution of the Latino Population



for a total of 85% of Latinos concentrated in 23 communities out of the 77 communities that comprise the city (Table 1).

The areas of concentration of Latinos and, more specifically, the subareas of Latino clustering are among the most deteriorated and oldest in Chicago. Out of 41,667 housing units lost by the city to deterioration between 1980 and 1983, 45% are located in the 23 communities of highest Latino concentration, particularly in their Latino and black subsections (Puente & Vásquez 1989). Considered ports of entry or lower-income communities, all of them have lower mean household incomes than the city and all but three have per capita incomes below those of Chicago. In each of them, Latinos have lower per capita incomes and more persons per room than the total population.

Latinos are not integrated with other groups in these areas. They tend to live in subclusters within census tracts, particularly in rental sections. They are less segregated than blacks in the sense that they live interspersed with other groups, particularly in areas in transition. Yet their clustering in specific blocks, buildings, or subsections of communities is visible to anyone. This is reflected in Figure 3, which shows a core of high concentration in or near their original clusters surrounded by contiguous census tracts with less concentration.

Ten percent more non-Latino households live in owner-occupied units in these areas than Latino households (Table 2). In other words, not only do Latinos live in the worst housing, but in rental housing. Notice that these are low-income areas. Hence, Latinos continue having the worst conditions even in the low-income areas in which they are concentrated in Chicago. This may also reflect the transitional nature of many such areas.

An examination by census tract shows that in 1990 Latinos paid more rent than non-Latinos in 360 of the 764 census tracts in the city. The average difference was $69 or 26% more than the rest. In contrast, they paid less rent in 404 tracts. The difference here was lower, at an average of $43 or 15%, suggesting that those who paid less were closer to the average than those who paid more. Nearly half of the tracts (49.4%) in which Latinos paid more rent were located in areas with 20% or more Latinos compared to 34% of those in which they paid less. Higher rents in areas of clustering may be associated with local scarcity resulting from concentration or from adjustments to Latino-related losses in housing prices. Lower rents in areas of lesser Latino presence may be related to the lower condition of housing rented to Latinos. As suggested by a study of the *Chicago Reporter* ("Hispanics and Asians" 1990), Latino and Asian areas are also the hardest hit in the city by rent increases.

A few citywide indicators help complete this picture. The percentage of owner-occupied housing units in 1983 was 31.4 for Latinos, compared to 33.8 for blacks and 48.8% for whites. A total of 90% of Latinos, 65% of blacks, and 61% of all households lived in housing built before 1939 (Puente & Vasquez 1989). Eighteen percent of Latinos lived in overcrowded housing in 1983 compared to only 10% of blacks and 7% of the total population (Puente & Vásquez 1989). While 58% of Latino households moved between 1980 and 1983, the figure for both blacks and all households was only 38%. A remarkable 71% of Latino renters moved in the period, compared to 50% of blacks and 55% of all renters (Puente & Vásquez 1989). More than 42% of Latino renters qualified for public housing in 1983 — compared to 33% of blacks and 23% of all renters. Only 1.7%

FIGURE 3: City of Chicago by Race and Ethnicity

of all public housing units were occupied by Latinos, 85.9% by blacks, and 11.9% by whites (Puente & Vásquez 1989). In that same year, only 2% of Latino renters lived in subsidized housing in the city compared to 20% of all blacks and 10% of all renters. In the 10 communities with the highest Latino percentages in 1980 and 60% of the Latino population of the city, only two out of ten households were occupied by Latino homeowners (Puente & Vásquez 1989).

Hence, Latinos were concentrated in the oldest areas and housing stock in the city, had the lowest homeownership rates, the highest concentration in mid-size, multifamily rental buildings, the lowest value homes, and the highest levels of overcrowding and residential mobility among all groups. They also paid a higher share of their income in rents and mortgages than whites.

This analysis and these findings are from within the city limits of Chicago, and we need also to examine the details from the suburbs. From an aggregate analysis, Massey and Denton (1988) argue that the levels of segregation in the suburbs are lower for all groups; while the segregation of blacks is still high, that of Latinos and Asians ranges from low to moderate. Examining this situation in detail for the suburbs of Chicago is beyond the scope of this article. Our preliminary assessment, however, suggests the possibility that many of the situations described for Chicago hold there as well.

First, large suburban Latino concentrations are often expansions of clusters established around World Wars I and II. Their process of formation is similar to the one described for Chicago. In fact, they resulted from the direct importation of workers by railroad and manufacturing employers (Año Nuevo Kerr 1976). Second, Latino increases have taken place particularly in old suburbs of white flight, disinvestment, and deindustrialization. Even though suburban Latinos are slightly better off than Latinos in the city, their suburbanization is proceeding

along the lines of clustering in the most deteriorated rental areas (Latino Institute 1993). Third, Latino concentrations may not be easily captured by analyses at the census-tract level because they are often located in smaller enclaves around multifamily rental housing or because their suburban growth is too recent to show definite patterns. Many of their enclaves have become important reservoirs of low-wage labor for the suburban economy. Preliminary research in the suburbs of the northwest points to the clustering of Latinos there (Tobias & Roy 1993). Our own analysis shows, in nine of the ten suburbs with the largest Latino populations, concentrations in a few census tracts far above the overall Latino percentage. In eight of them (Addison, Aurora, Blue Island, Chicago Heights, Cicero, Joliet, Melrose Park, and Waukegan), with Latino populations ranging from 13% to 37%, between 39% and 74% of Latinos are concentrated in three, mostly contiguous, census tracts. Then, in the suburb of West Chicago, 30% Latino, 61% of the Latino population is clustered also in one single tract.

Fourth, some of the most dramatic growth has taken place in suburbs immediately contiguous to the city. In fact, they continue the expansion of current Latino concentrations in Chicago. Fifth, incidents of discrimination seem to be growing with increases in the population and concentration of Latinos. The cases of Cicero, Hodgkins, Waukegan, and Addison where Latino groups are challenging efforts by these municipalities to displace them through renewal and code enforcement in their areas of residence illustrate this.[28] A study by the *Chicago Reporter* ("Suburban Housing" 1995) of six suburbs where the Latino population doubled in the 1980s concluded that Latinos were getting a disproportionate share of code enforcement efforts in these suburbs. Sixth, many suburbs with significant Latino populations have large and growing black concentrations, often bordering Latino clusters. Seventh, the trend in some suburbs is toward a Latino majority in the near future. In short, this evidence calls for analyses of the suburbs at a disaggregated and qualitative level to identify elements of segregation and discrimination that cannot be captured by the indexes and other aggregate analyses used in support of the ecological model.

Conclusion

This analysis has identified many elements of discrimination in the Latino residential experience in Chicago. It suggested the existence of a "Latino rent" and a high level of manipulation of their settlement process. It illustrated the extreme vulnerability and instability of Latino communities associated with their status in the U.S. and the resulting "racialization" of their settlement. It argued that Latino status is a source of segregation and speculation in the city's housing market. As Latino settlement intensifies or expands, adjacent white areas become less desirable and are progressively disinvested and thus opened up to Latinos. Once Latinos enter them in large numbers, they are also opened to blacks and the process of transition and disinvestment intensifies. Along the way, Latinos often become a buffer between blacks and whites. They provide owners with the opportunity to recover their investment, in fact, to engage in

discriminatory speculation based on the Latino condition. From this perspective, it could be argued that Latinos end up facilitating, if not financing, white flight. On these bases, the article questions Massey's claim that Latinos are "ethnics" properly represented by the ecological model.

Our research also suggests that clustering has been strongly associated with Latino status in Chicago. While choice and common characteristics are important factors, exclusion associated with a Latino status has intensified and perpetuated it. Similarly, the article suggests that dispersal is not followed by assimilation as in the ecological model but by reconcentration. It is often the result of displacement, disinvestment, overcrowding, and the instability associated with low ownership, immigration status, back and forth migration, and unstable unemployment related to Latino status. Residential mobility, then, is largely horizontal. Higher-income Latinos often move to the fringes of Latino areas while maintaining a close association with their clusters of origin. Like blacks, others may be able to move into white areas individually. As their numbers increase, however, their presence is increasingly resented and may set up the process of white flight.

This article linked the condition of Latinos to the terms of their immigration and the domination associated with their origin and minority status. While, generally, European ethnics had high levels of mobility within and between industries and occupations leading to socioeconomic mobility, Latinos were segmented into marginal, unskilled jobs that froze them at the bottom. In the model, residential and socioeconomic mobility are closely related. In contrast, subjugation and "racialization" have denied Latinos substantial economic assimilation and have subjected them to multiple forms of segregation unaccounted for in the ecological model.

Our research points to the importance of qualitative analyses for identification of explanations and elements that statistical tests often miss. It, in fact, suggests interpretations of Latino settlement different from those of the ecological model. While the levels of Latino segregation are lower than those of blacks (Massey & Denton 1987, 1993), this may be the result of the higher mobility and instability discussed rather than of the integration and mobility implied by the model. "Integration" may be a phenomenon of an area's transition. The high resilience of original Latino clusters may be related to anti-Latino prejudice and exclusion. Dispersal into adjacent white areas is often only the beginning of the turnover process. Higher-income Latinos may be the ones moving first, as they have the choice of homeownership and provide whites with the opportunity to exit areas adjacent to Latino clusters. As this movement to the fringes intensifies, more whites leave and rent to Latinos. In fact, a high correlation between socioeconomic status and mobility away from Latino cores may result from the pioneer role of higher-income Latinos (Aguirre, Schwirian & LaGreca 1980; Jackson 1981; Massey 1979; Valdez & Jones 1985).

Thus, the settlement of Latinos in Chicago differs in significant ways from the pattern and assumptions of the ecology model. Unlike Europeans, Latinos bear a permanent minority condition that has translated into exclusion, economic immobility, and manipulation. This is reflected in a settlement process deeply colored by discrimination. U.S. society has extended racism to Latinos; their settlement reflects this. Moreover, ongoing national economic restructuring

pointing to a shrinking of middle classes and opportunities, to a highly polarized labor market, and to the intensification of the disadvantages of minorities (Harrison & Bluestone 1988) casts further doubt on the future applicability of the ecological model to Latinos.

Meanwhile, the dynamics of racism have separated Latinos from other minorities. Once excluded, Latinos and blacks have turned their segregated communities into a basis for struggle, often to the exclusion of each other. As a result, the pattern of separation is intensified. As disinvestment destroys black areas, blacks start pushing outside their borders and entering areas frequently opened first to Latinos. It is not as much a matter of choice and succession as a matter of segregation and market manipulation. We should not equate these dynamics to "ethnic" succession and upward mobility.

The continuous influx of Latinos may feed into their areas of first settlement and reinforce their concentration. This factor needs to be examined in detail. Evidence suggests that in nearly a century of Latino immigration to Chicago, patterns of segregation and dispersal have been continuous. Residential assimilation has never been close to the levels of European immigrants. Tension and real-estate speculation related to Latino status may be fed by new entrants. Low levels of tension associated with recent or continued European influx, though, point to prejudice in the case of Latinos. This prejudice, indeed, extends to middle-class and U.S.-born Latinos and is reflected in the reaction to increases in the proportion of Latinos in white areas. Suburbanization of Latinos may conceivably fit the model. Limited evidence available for the Chicago suburbs, however, suggests that the suburbs are experiencing the same general trends of clustering, segregation, and dispersion as the central city. Detailed testing of these claims is necessary to gain a complete understanding of the settlement experience of Latinos in Chicago. Finally, other models need to be developed or further examined for alternative explanations of the Latino experience.

Notes

1. Discrimination against Latinos has ranged from subtle forms of exclusion to more open ones of labor segmentation (Meléndez 1988; Meléndez, Rodríguez & Figueroa 1991) and immigration status (Kirstein 1977; Kiser & Kiser 1979). While some of them have been documented, most others have not. In fact, research on Latinos in the U.S. lags far behind that of blacks and European immigrants.

2. Little attention has been paid to the relationship between U.S. domination of Latin America, the terms of migration, and the conditions of Latinos in the U.S. Latin Americanists are aware of the use of migration as a tool in the domination of the region. Analysts of the Latino experience in the U.S. know about the coalition of the U.S. government and employers for importation of Latinos on terms leading to their labor segmentation and overexploitation. The combination of their actions has produced a highly vulnerable Latino population with conditions, status, and treatment similar to those of American Indians and blacks.

3. We focus on Puerto Ricans and Mexicans because they are 65 and 23% respectively of the Latino population in Chicago. We are aware, however, that the individual cases of other Latino subgroups need to be examined in detail, as their experiences may differ from the experience identified here.

4. These were nonunion, labor-intensive industries relying heavily on immigrant labor. Latinos not only were assigned unskilled jobs but had minimal mobility through the ranks (Rosales &

Simon 1978; Taylor 1932). This translated into a high concentration of Latinos in such industries and occupations — as late as the 1980s (Año Nuevo Kerr 1976; Betancur, Córdova & Torres 1993).

5. Employers encourage Latino employees to bring friends, relatives, or others they know. This gives them some guarantee that the recruits are of the same quality. Moreover, the recommending party makes sure that the other person works out.

6. One case in point is the Bracero Agreement between the U.S.A. and Mexico in World War II to import Mexicans for temporary work in occupations and industries for which there was a labor shortage. The agreement explicitly indicated that braceros were not to compete for jobs for which U.S. labor was available (Kirstein 1977:15-24). In this way, Mexicans were once again limited to low-end jobs in labor-intensive industries. Labor segmentation ensued as employers continued pursuing Mexicans for these types of jobs.

7. Mexicans were blamed in the Great Depression for taking "the jobs of Americans" (Rosales & Simon 1978). "Repatriation" was largely a result of this. Undocumented workers have been blamed and selectively raided and deported in every economic downturn. Proposition 187 in California and the wave of sentiment against the undocumented and against immigrants in general is the most recent expression of this. In the 1940s, on the occasion of a confrontation between servicemen partying in a Mexican neighborhood in Los Angeles and local youth, the national press blamed Mexicans and branded them as subversive, unredeemable, and opposed to the war. Special outreach efforts took place next in U.S. cities, under the assumption that Latinos, especially youth, were particularly vulnerable to subversive influences (Año Nuevo Kerr 1976). Latinos have been stereotyped as violent, noncompetitive, lacking the proper values and drive for success, etc. And their condition has been often blamed on this.

8. Acquired in the Spanish-American War of 1898, Puerto Rico became a heaven for U.S. investment and a source of cheap labor for the U.S. economy. The U.S. extended the model of dependent development of Latin America to the island. Strong independence sentiments developed during Spanish tenure of the island were then directed toward the U.S. The conflict with the U.S. and the model of development became a continuous source of tension in the island.

9. In its Statement of Motives of 1947, Puerto Rico announced that it would cooperate with mainland agencies in the settlement of immigrants and guide them to areas of labor demand (Maldonado 1987). An agency of the Department of Labor of Puerto Rico was established in Chicago in 1949 to facilitate the recruitment of Puerto Ricans for work in the city and the Midwest (Martínez 1989). Private recruiters such as Castle, Barton and Associates and the Friedman Farm Labor Agency imported Puerto Ricans for firms such as the Chicago Hardware Foundry Company and U.S. Steel. Castle also provided households with maids from the island (Martínez 1989).

10. Arranged migration refers to the unique terms of Latino importation discussed in this section. Arrangements such as temporary admissions or undocumented migration produced a highly disadvantaged group of "illegal," second-class, or transient workers. Importation for strikebreaking set them against white workers while recruitment for marginal industries and occupations turned them into a highly segmented labor pool. U.S. actions in Latin America generated political and economic refugees that were often used to wage counterrevolutionary drives in the region. Latino migration often became a revolving door, and Latinos became immigrants of last resort with highly unstable or vulnerable statuses, "illegal aliens," second-class immigrants, or an imposed presence on America that was resented by other workers and groups.

11. Evidence indicates that the importing companies had to play a role in housing Mexican workers in order to guarantee their migration. Housing scarcity particularly near the areas of employment was a factor. In the case of workers recruited to replace strikers, housing them inside the company grounds was crucial.

12. The words of a realtor quoted by Taylor (1932) illustrate this: "Mexicans depreciate property values and take the jobs of others. When the Mexicans come in, the others say they want to sail out" (222).

13. Interviews of Mexican residents of the Hull House area reveal that urban renewal and real-estate agents had steered them to Pilsen.

Mexicans stabilized and started reversing the decline. Today, it is among the oldest and most overcrowded areas of the city. Slightly over half of its units are overcrowded, compared to 27.3% for Chicago as a whole. Three-fourths are rental units. Even though Latinos were nearly four-fifths of residents in 1980, they owned under half the owner-occupied units.

15. As blacks gained control, they "marked these communities off" as their "exclusive domain" (Padilla 1987:85). Puerto Ricans felt that "Blacks would never voluntarily yield any of the benefits or resources" of such places (85). "Racial problems or social misunderstandings with Blacks resulted in the movement of Puerto Ricans from these areas" (86).

16. Again, Puerto Ricans had lived on the Near North Side, close to downtown. With urban renewal, they were pushed west into the adjacent communities of West Town, Humboldt Park, and Logan Square. As the South Side and East Side areas they originally lived in became black, in the 1970s they joined the cluster on the Near Northwest Side in large numbers to form their own neighborhood.

17. Promoters of gentrification in Wicker Park, a subsection of West Town, explain that they acted to save the architectural and historical value of the area from the deterioration associated with Puerto Rican residents.

18. Our fieldwork indicates that former homeowners were able to buy in adjacent areas because of the "high prices" obtained from their properties. Often, however, they purchased smaller houses. Others had to double or triple up with relatives to buy. Tenants reported moving many times near their original quarters, often having to double up because of the higher rental price of the new units. The result of this has been increased overcrowding in subsections of adjacent communities.

19. As Latinos move in, the value of housing decreases along with the desirability of the area. Disinvestment intensifies or follows, further devalorizing the area. Devalorization may then create an opportunity in the gap between the rent currently realized and the one that could be realized through reinvestment (Smith 1979).

20. In Pilsen, Latinos went from 55% of the residents in 1970 to 88% in 1990; in Back of the Yards from 13% to 39%; in South Chicago from 26.1% to 33%; in West Town from 39.1% to 62%; in Logan Square from 17.8% to 66%; and in Humboldt Park from 15.5% to 49%.

21. In Back of the Yards, blacks surpassed Latinos in the period 1980-90, growing from 22 to 41%. In South Deering, they went from 54% to 59% (Latinos increased by a mere 241 persons here). Blacks in South Chicago went from 22.4% in 1970 to 48.8% in 1980, and to 61% in 1990, surpassing the declining Latino population. South Chicago lost 5,656 people in the 1980s.

22. Blacks, in fact, went from 35% to 49% in Humboldt Park between 1980 and 1990 to equal the Latino population in 1990. They remained stable at 9% in West Town and went from 2% to 5% in Logan Square. This expansion is related to the increasing deterioration of black communities to the south — the West Side of Chicago.

23. South Lawndale has one of the oldest housing stocks in Chicago. Having achieved majority in Pilsen, Latinos moved southwest into South Lawndale to become 31.9% in 1970, 74% in 1980, and 85.2% in 1990. South Lawndale is also predominantly a rental community with only 34% of its units owner occupied, over half of them (57%) owned by Latinos in 1980. Pilsen and South Lawndale have among the lowest vacancy rates and the highest rates of overcrowding in the city.

24. Traditionally a stable white working class area in which "homes are handed down from generation to generation" (Chicago Fact Book Consortium 1984:138), the East Side has become increasingly Latino (from 13% in 1980 to 40% in 1990).

25. Latinos are highly concentrated in subsections of these areas, forming a continuum with other Latino areas or with subsections of adjacent clusters. Typical resident-owner areas, Brighton Park, McKinley Park, Bridgeport, and Gage Park have been increasing their rental housing as whites move out. Traditionally closed to nonwhites and the scenario of many racial conflicts, the last two areas have opened up as the combined result of white decline, disinvestment in the city and the growth of the Latino population.

26. Hermosa, Avondale, Albany, North Center, Lincoln Square, Belmont-Cragin, and Irving Park are all adjacent, traditionally white communities. As Uptown to the east and Logan Square and Humboldt Park to the south increased their Latino and black populations, whites started leaving and opening the door to others. With the exception of Belmont-Cragin, all these

areas are largely rental. Albany and North Center have an extensive stock of multifamily buildings. The others have a mix with a predominance of small two- to four-unit buildings. Latinos are concentrated in rental units, usually in the most deteriorated sections.

27. Gentrification in Chicago has taken place mostly in Latino areas. Location near downtown and the architectural value of their housing made them particularly attractive. The vulnerability and high levels of Latinos renting facilitated this.

28. As was noted in the 7 October, 1994 edition of the *Chicago Tribune,* Latinos filed a lawsuit in Addison claiming that redevelopment plans for a section of the municipality are discriminatory and violate the civil rights of Latinos. This suit was joined by the U.S. Justice Department, which accused Addison of violating the federal Fair Housing Act. Meanwhile, in 1993 this same department sued the suburb of Cicero on grounds that its occupancy ordinance was discriminatory against Latinos, as was described in the *Chicago Reporter*, September 1995.

Segregation and Crime: The Effect of Black Social Isolation on the Rates of Black Urban Violence*

EDWARD S. SHIHADEH, *Louisiana State University*
NICOLE FLYNN, *Louisiana State University*

Abstract

Prior segregation-crime research has failed to recognize that segregation has many geographic forms and each may have a distinct macrosocial path to crime. We sharpen the conceptual link between segregation and crime by considering how the social isolation of urban blacks increases black violence. Using race-disaggregated Uniform Crime Report (UCR) and census data for 1990, we examine the link between black social isolation and the rates of black homicide and robbery in U.S. cities. In contrast to previous research, which employs the index of dissimilarity (D) as a default indicator of segregation (which it is not), we measure the spatial isolation (P) of blacks from whites. Black isolation emerges as a strong predictor of the rates of black violence in major U.S. cities, a finding that may account for prior evidence of a link between segregation and violence at the macro level.

High levels of violence in urban black communities are a widely acknowledged though often neglected research issue. While homicide rates in the U.S. are among the highest in world, of particular concern is this country's disproportionately high rates of minority crime. For instance, while blacks comprise only about 12% of the U.S. population (Current Population Reports 1988), they account for over one half of homicides and about two-thirds of robbery arrestees (U.S. Dept. of Justice 1988). About 50% of all black urban males are arrested for a serious crime at least once, compared to only 14% of white urban males, and blacks are six times more likely to spend time in prison or jail (Petersilia 1985).

There is a growing concern that high rates of violence in black communities may be related to black-white residential segregation in urban areas. Indeed, while minority segregation in the U.S. cities is pervasive, black spatial segregation is particularly entrenched and appears to be highly resistant to change

* *We are grateful to Katharine Donato, Scott Feld, Daniel Lichter, Roger Wojtkiewicz, and the anonymous reviewers for helpful comments.* *Direct correspondence to Edward S. Shihadeh, 126 Stubbs Hall, Department of Sociology, Louisiana State University, Baton Rouge, LA 70803*

 Social Forces, June 1996, 74(4):1325-1352

(Farley & Frey 1994; Massey & Mullan 1984; Massey 1990; Massey & Denton 1988, 1993). One especially pernicious outcome of black-white segregation is in how it socially isolates many urban blacks from mainstream society. Recent research on the rise of the urban underclass and the ghettoization of black inner-city areas suggests that the geographic isolation of low-income urban blacks from white-dominated neighborhoods has anchored many black residents to areas of multiple disadvantage (e.g., Massey & Denton 1993; Wilson 1987, 1993). This creates a significant barrier to the social mobility of many urban blacks in the U.S. and may contribute to the rates of violence in black communities.

While the handful of studies that have examined the relationship between segregation and crime have been instructive, they contain several important limitations. First, they have relied heavily on the notion that segregation is an ascriptive form of inequality that generates high crime rates by creating hostile sentiments and/or a weakened attachment to social norms restraining the use of violence. Unfortunately, this approach ties the study of segregation and crime to a body of research that has provided mixed and inconsistent evidence of a link between inequality and crime (see review below). It also assumes that the crime-producing mechanism of segregation is the same as it is for other forms of inequality (e.g., income inequality, educational inequality). However, recent research on segregation and the social isolation of the underclass suggests that this may not be the case.

Second, previous studies view segregation in only one way — as the degree of spatial *unevenness* in the distribution of blacks versus whites. However, segregation has a number of empirically distinct distributional forms (Massey & Denton 1988). The exclusive focus on spatial unevenness as a default indicator of segregation fails to capture other theoretically relevant dimensions of residential segregation — namely the social isolation of blacks from whites. And third, while several studies disaggregate crime rates by race, rarely are they concerned with measuring the direct impact of segregation on crimes committed by blacks. This raises a concern since both segregation and its possible outcomes, such as serious crime, are problems faced mainly by black communities.

We extend the research on segregation and crime by suggesting an alternative causal mechanism by which segregation generates violence. Our objective is to examine the impact of one specific form of segregation, black isolation from whites, on the rates of black violence in U.S. cities for 1990. We begin by discussing the theoretical link between black isolation and black urban violence. A brief simulation is then presented in order to clarify the distinction between black-white spatial unevenness — which is the more commonly used dimension of segregation — and black isolation from whites. We then estimate several models predicting racially disaggregated rates of homicide and robbery, using an indicator of black isolation and a variety of racially disaggregated predictors. Our analysis concludes with a discussion of the theoretical and methodological implications of the findings.

Black Residential Segregation and Crime

Though racial discrimination in the sale and rental of housing was banned by the Civil Rights Act of 1968, an enduring feature of urban areas in the U.S. is the extreme residential segregation of blacks. Despite the liberalization of white attitudes, endorsing the principle of integration has been easier than accepting black neighbors (Farley & Frey 1994). During the 1980s, the average black-white index of dissimilarity in major metropolitan areas was exceedingly high and declined only modestly, from an average of 69 to 65 from 1980 to 1990. Massey and Denton (1993) argue that the source of black segregation is in a legacy of white discrimination against blacks, producing a physical separation of the races and an isolation of many blacks from mainstream residential communities and institutions. Blacks are discouraged from settling in white neighborhoods in order to preserve the racial character of the area. Alternatively, whites abandon communities with a growing black population, producing a line of retreating white neighborhoods in the face of black residential expansion. In any case, blacks lack equal opportunity in housing and are more likely to be tied to communities with multiple disadvantages, where the rates of unemployment, poverty, school dropout, family disruption, and teen pregnancy are disproportionately high. By blocking channels to social and economic mobility and undermining the legitimacy of established social norms, high rates of residential segregation are presumed to generate various forms of deviance and violent behavior.

While evidence suggests that residential segregation has a number of negative outcomes, comparatively little is known about its relationship with respect to crime (Logan & Messner 1987; Messner & South 1986; Peterson & Krivo 1993; Potter 1991; Rosenfeld 1986; Sampson 1985; South & Felson 1990). Messner and South (1986) and South and Felson (1990) find that segregation tends to increase rates of *intra*-racial victimization, but decrease rates of *inter*-racial victimization. Logan and Messner (1987) examine the impact of segregation on violence rates in the suburbs of large urban areas and report a positive relationship between segregation and murder for 1980, but not for 1970. Rosenfeld (1986) finds an empirical association between homicide rates and segregation in large U.S. metropolitan areas in 1970. Among those that directly test the impact of segregation on black crime, Sampson (1985) reports the unexpected finding that segregation predicts homicide rates among whites but not blacks. In contrast, Potter (1991) finds that segregation is related to the black-white difference in homicide rates, and Peterson and Krivo (1993) find that segregation predicts stranger and acquaintance homicide among urban blacks in 1980.

While these studies are instructive, they are problematic and thereby limit a thorough understanding of how the residential segregation of blacks generates high crime rates. First, there has been a heavy reliance on the notion that segregation as an ascriptive form of inequality generates violence by causing frustration and aggression and by weakening the attachment to conventional normative structures. In the most prominent statement of that thesis, Blau and Blau (1982) use a frustration-aggression framework to argue that inequality based on ascriptive characteristics such as race can lead to hostile sentiments

which, in extreme cases, find expression in the form of violence. Extending Merton's work on social structure and anomie, Logan and Messner (1987) have argued that inequality is a system disjuncture that weakens the legitimacy of social norms and reduces the capacity of communities to exert social control.

Unfortunately these arguments tie the analysis of segregation to a body of research that has produced mixed results and conflicting evidence regarding a link between racial inequality and serious violence. Our audit of the literature reveals that while some find support that inequality directly increases crime rates (Blau & Golden 1986; Blau & Schwartz 1984), most find either partial support (Balkwell 1990; Messner & Golden 1992; Sampson 1985; Williams 1984) or no support at all (Balkwell 1983; Carroll & Jackson 1983; Shihadeh & Steffensmeier 1994; Harer & Steffensmeier 1992; Patterson 1991; Rosenfeld 1986). We agree that segregation is one dimension of a racially stratified system. What troubles us is the underlying assumption that the crime-producing mechanism of black-white residential segregation is the same as that identified for other types of racial inequality (e.g., inequality by income, education, occupational prestige, etc.). Perhaps the research on segregation and crime can be enhanced by identifying specific causal paths by which the geographic separation of the races leads to high rates of minority crime.

Second, previous segregation-crime research has examined only one form of segregation, the spatial *unevenness* between blacks and whites. Typically calculated using the index of dissimilarity (*D*), urban blacks are considered segregated if their residences are unevenly distributed across areal units with respect to those of whites. But Massey and Denton (1988) identify five forms of black-white segregation and each is conceptually and empirically independent of the other (unevenness, isolation, centralization, concentration, and clustering).[1] These are not five measures of the same phenomenon, but five distinct ways in which two or more groups live separately from one another . Thus, the practice of using unevenness (*D*) as the generic form of segregation, rather than as merely *one* form, is unwarranted since unevenness in spatial distribution does not represents all forms of segregation. Moreover, previous research has not provided a rationale as to why unevenness, versus other forms of segregation, is the most appropriate match for the theories under examination. Perhaps a more informed understanding of how segregation engenders violence requires that we focus on one particular distributional characteristic of black-white segregation and then identify a specific theoretical mechanism linking it to violence.[2]

Finally, with the exception of Sampson (1985) and Peterson and Krivo (1993), previous studies have not examined the direct impact of segregation on *black* violence. Yet it is reasonable to expect that the negative consequences resulting from segregation are directed mainly towards the minority in question, not the population as a whole. Since blacks bear the brunt of the adverse effects of black-white residential segregation, research should focus more closely on the specific outcomes to their communities. Indeed, recent evidence suggests that the macrosocial paths leading to high rates of black urban violence differ from those contributing to high rates of white urban violence (e.g., Harer & Steffensmeier 1992; Huff-Corzine, Corzine & Moore 1986; LaFree, Drass & O'Day 1992; Sampson 1987; Shihadeh & Steffensmeier 1994). Evidence also suggests that

crime models that use nonracially disaggregated data mask potentially important race differences in the sources of urban violence.

In brief, the evidence indicates that segregation is an embedded feature of urban areas in the U.S. and may have a variety of negative outcomes on the lives of many black residents. The results from several studies suggest that black-white residential segregation contributes to the rates of violent crime, particularly among blacks. However, the knowledge of the theoretical and causal nature of this relationship remains very limited. Our objective is to contribute to our understanding about the consequences of segregation and the macrosocial paths leading to black violence by considering recent research on the rise of the black urban underclass.

BLACK SOCIAL ISOLATION

Among the various ways that blacks can be segregated from whites, one particular form, *black isolation*, exists when the degree of potential contact between blacks and whites is low. Because of perpetuating institutional arrangements and individual actions, blacks face considerable difficulty in accessing nonminority neighborhoods. Blacks are excluded from white areas either through subtle means, such as the denial of mortgages, or by direct threat and intimidation. Conversely, whites are inclined to move when their preference for limited interracial contact is threatened by an influx of blacks (Farley et al. 1978; Farley et al. 1994). The resulting limited contact between blacks and whites may isolate many blacks from the rest of society and severely limit their chances for social mobility (Massey & Denton 1993; Massey & Mullan 1984; Wilson 1987).

Although other groups have experienced isolation, it is a particularly serious problem in urban black communities. First, blacks in the U.S. experience an isolation that is unprecedented and qualitatively different from that faced by other ethnic groups (Massey & Denton 1993). Although certain parts of a city may have been publicly identified with a particular immigrant-ethnic group, such as Italian or Polish, these areas, even during the height of immigration, have never shown the degree and persistence of isolation found in low-income black communities (Massey & Denton 1993; Philpott 1978). Indeed, among the ten largest U.S. cities in 1980, the average black lived in a neighborhood that was in excess of 80% black, and the vast majority resided in areas that are were 100% black (Massey & Denton 1988). Second, black isolation not only isolates blacks themselves, but also the negative characteristics that are collinear with black urban life. Black isolation combines the weight of poverty, joblessness, welfare dependency, teenage childbearing, and other indicators of social malaise and concentrates them geographically in black neighborhoods (Wilson 1993). Social isolation is a problem for many black-dominated areas not because these communities have some intrinsic weakness in their adaptation to negative structural conditions, but because these unprecedented levels of isolation converge a set of multiple disadvantages into a single ecological space.

In broad terms, spatial isolation leads to social isolation, which in turn has a variety of negative outcomes including serious crime. Below, we discuss a number of ways how black isolation can lead to the economic, cultural, and

political decline of urban black communities. The logic of our argument is not hinged on any single reason, but on a combination of following possible consequences of black isolation. Our analytical objective is to establish whether a cross-sectional relationship exists between black social isolation and serious black crime across major cities in the U.S. However, for background and theoretical clarity we recognize in the discussion below that the relationship between black isolation, the structural characteristics of urban areas, and serious crime is processual in nature — as is the relationship between other social factors.

Economic Factors

One of the major concerns of black isolation is that it may undermine the attachment of low-income blacks to the labor force. Unless residents of low-income black areas work outside the neighborhood, they are unlikely to have sustained contact with anyone else who is not black and who has steady employment (Pedder 1991; Yancey 1985). The effects of this structural constraint loom large when one considers that in central cities 54% of black men aged 18-29 are either out of the labor force, unemployed, or underemployed (Lichter 1988). Massey and Denton (1993) lament that the residents of these neighborhoods "necessarily live within a very circumscribed and limited social world. They rarely travel outside of the black enclave, and most have few friends outside of the ghetto . . . Because blacks have weak links to white society, they are not connected to the jobs that white society provides" (161-62). This does not imply that ghetto residents have a reduced willingness or motivation to work. Rather, with limited access to job information systems and a lack of successful role models, many blacks are disadvantaged in the competition for employment, particularly given the shrinking base of low-skill jobs in central cities (Kasarda 1990). The inevitable result is a weakened labor force attachment among large segments of center-city blacks that "raises the likelihood that [*they*] will turn to illegal or deviant activities for income, thereby further weakening their attachment to the legitimate labor market" (Wilson 1993:21).

An underlying source of black isolation may be the loss of the black middle class to the more affluent areas in the suburbs, which removed the vertical integration of many center-city black communities and transformed them into areas of concentrated poverty (Wilson 1987, but see Massey, Gross & Shibuya 1994). While black suburbanization may have contributed to the economic decline of black inner-city neighborhoods, a contributing factor may be a downward mobility among middle-class stayers in these areas. Residents who remain behind find that one of the most important sources of middle-class capital accumulation, housing value, is steadily eroded. As the neighborhood declines, housing stock deteriorates, and institutional decisions by banks and insurance companies make it difficult to acquire reasonable mortgages and insurance (Bradford & Rubinowitz 1975; Urban-Suburban Investment Study Group 1975), a practice known as "redlining." Signs that the neighborhood is declining create a self-fulfilling prophecy that leads to a downward spiral in property values and a corresponding decline in the wealth of anchored residents (Skogan 1992). Thus those left behind in declining areas will experience downward social mobility as home equity disappears. Moreover, if home equity

is a conduit to other sources of capital, such as auto and consumer financing, or college and small-business loans, structural declines in home value could further distance local residents from mainstream economic and social opportunities.

Cultural

If members of ghetto communities are influenced by the beliefs, modes of behavior and the experiences of relevant others around them, black isolation may produce an inversion of mainstream values that further increases the social disability of blacks. This is not a culture of poverty perspective, which focuses on negative subcultural and personality traits that acquire a life of their own and continue to influence behavior even when structural conditions improve (Banfield 1974; Curtis 1975; Gastil 1971; Lewis 1961, 1968). Rather, we emphasize how oppositional ghetto practices are proximate outcomes to a structural condition of social isolation. For instance, Elijah Anderson (1993, 1994) uses ethnographic research to link certain ghetto-specific practices to black social isolation. He maintains that because many young blacks are isolated from the white economy and white job networks, they have little hope of acquiring meaningful employment sufficient to support a family. They are deprived, therefore, of the primary conduit by which adult men in mainstream society prove their worth. Instead they turn to male peers for support and assert their manhood by fostering a self-image based on violence. Anderson argues that ghetto-specific practices, such as overt sexuality, gang membership, and open displays of aggression reflect the emergence of an alternative status system that legitimates behaviors that would be held in contempt by the wider society. He further notes that clothing, jewelry, hair styles, facial expressions, and gait are all used to shore up an identity of physical toughness. Even young men with otherwise nonviolent predispositions feel compelled to assume a street-oriented demeanor, emphasizing a distinctive linguistic pattern (Labov 1980) and the willingness to use violence (Anderson 1994).

Anderson (1990) also emphasizes how social isolation in black ghettos can invert conventional values about childbearing. Traditional standards stress that pregnancy should follow marriage, or vice versa, and should be accompanied by financial stability. But the female subjects he interviewed in ghetto areas appeared to reject that notion. On the contrary, a conduit to recognition and prestige among girls and young women in the ghetto appeared to be childbearing itself, regardless of the trappings of marriage or cohabitation and financial stability. This ideology is countercultural in that those women who have children have acquired adult status in the eyes of peers, while those without children have not. But since mother-only households make up a disproportionate share of the poor, this leads to legitimate concerns about the intergenerational transfer of poverty (McLanahan & Booth 1989). Much of the extant crime research has generally failed to yield evidence of a significant individual-level relationship between family structure and crime — that single-parent households are more likely to produce juvenile delinquents (Ensminger, Kellam & Rubin 1983; LaFree, Drass & O'Day 1992; Ross & Sawhill 1975; but see Matsueda & Heimer 1987). Yet at the aggregate level, Sampson (1987) and Shihadeh and Steffensmeier (1994) find extremely strong associations between the rates of black female-headed household and the rates of black violence. They

argue that when single-parent households are the norm, this weakens the formal and informal capacity of communities to exert social control over their members which in turn leads to higher rates of offending (see Shihadeh & Steffensmeier 1994). In any case, adaptations of household structure within isolated black communities represents a potentially important component of the segregation-crime link.

Black isolation further distances black residents from mainstream society by removing the stigma of economic and social failure, and weakens the capacity of major institutions to socialize and control their members. For instance, it can devalue education and even impose a direct social pressure for educational failure (Crain & Mahard 1978; Fordham & Ogbu 1986). Many bright and motivated blacks in segregated low-income areas face enormous pressure not to succeed in school for fear of being labeled as too "white" by other kids (Fordham & Ogbu 1986). Worst of all, the social stigma of incarceration — perhaps society's harshest form of social control — is weakened. Brown (1984) suggests that a significant portion of young male ghetto residents view doing time in prison as a form of graduate school and a rite of passage to peer acceptance.

Political

Black isolation from whites may also lead to political and economic disenfranchisement of black neighborhoods (see discussion in Massey & Denton 1993). Historically, ethnically integrated neighborhoods formed the basis for powerful political coalitions (Dahl 1961, 1967; Pinderhughes 1987). Because no single ethnic group typically dominated white areas (Massey & Denton 1993), resources allocated to any specific ethnic group is of benefit to all members of the local community. Given this interweaving of interests, political representatives have to pay attention to the demands of a wide spectrum of voters, irrespective of ethnic affiliation (Pinderhughes 1987). The geographic isolation of blacks, however, undermines the power of pluralist politics and means that whites have less to gain when public funds and resources are channeled to all black areas and away from multiethnic communities (Edsall & Edsall 1991; Grimshaw 1980; Katznelson 1976; Kemp 1986; Spear 1967). Black isolation further contributes to the disinvestment and decline in many urban black areas by making them vulnerable to cutbacks in public funds and services. Rather than risk antagonizing white voters, white politicians are more apt to target black neighborhoods for spending cuts because of the minimal political fallout (D. Wallace 1990; R. Wallace 1991).

Limitations in the political influence of socially isolated black areas may reduce the effectiveness of traditional forms of neighborhood-level political expression. Social disorganization theorists emphasize how a network of informal and formal social controls maintain desirable conduct and conventional lines of action in a community (Bursik & Grasmick 1993; Kasarda & Janowitz 1974; Shaw & McKay 1931). But this type of control is *internal* to the community. In contrast, a public level of control concerns the ability of a community to control the *external* environment in order to procure government aid and services, as well as the passage or defeat of laws and ordinances favorable to the community (Hunter 1985). In general terms, public control refers to the use

of external political, social, or economic structures — such as local governing bodies — for the benefit of the local community (Bursik & Grasmick 1993). This public control embodies the capacity of the community to manipulate external resources in order to defend its interests (Hunter 1974). While membership in civic associations, churches, and participation in local politics is a conduit of this expression, its effectiveness in isolated ghetto areas may be very limited. Evidence suggests that residents of low-income black areas are less likely than otherwise-comparable blacks to be members of churches and local organizations and are less active in electoral politics (Brown 1991). Furthermore, lack of participation in community-based initiatives is a predictor of both adult and juvenile crime rates (Sampson & Groves 1989). Thus, in depriving blacks of political empowerment, social isolation may contribute to their economic and social decline.

While black isolation from whites may have a number of potentially harmful effects on the economic, cultural, and political structures in black communities, in a broader sense it can also be tied to the emerging ideas on social capital. Social capital refers to the structure of interpersonal relations and institutional linkages that facilitate effective ties that bind a person to the community or society and that enhance an individual's life chances. "Social capital is productive, making possible the achievements of certain ends that in its absence would not be possible" (Coleman 1988:98). Thus, social capital draws a strong connection between community-level processes and the lives of individuals. "Entire communities and countries, as well as the individuals within them, are locations of the accumulation of social capital" (Hagan 1994:69).

If social capital refers to the features of structured groupings that contribute to productive lives and conventional behavior, then those who lack access to it are at a disadvantage in seeking upward mobility (Bourdieu 1986). As a structured form of inequality, black isolation may reduce the accumulation of social capital in black communities for a number of reasons. If Bourdieu is correct — if economic capital is at the root of all forms of capital, including social capital — then the negative economic effects of black isolation will reduce the accumulation of social capital in black communities. But even from a cultural standpoint, communities extend social capital to members by cultivating values such as a work and family ethic, by instilling in males a sense of parental responsibility for children, and by creating confidence in the returns from education. These elements are critical for the transition from youth to successful adulthood in mainstream life, but social isolation may create conditions that hinder the capacity of black communities to extend these essential forms of social capital to their members.

In the following analysis, we go beyond previous segregation-crime research and examine the impact of black isolation on the rates of black urban violence. Initially, we run a brief simulation using hypothetical data in order to clarify the distinction between our measure, black isolation from whites, and the measure used in previous research, unevenness in spatial distribution. We then estimate models that incorporate racially disaggregated data for U.S. cities in 1990.

Data and Methods

The units of analysis in this study are the 151 U.S. cities with populations of 100,000 or more, and with at least 5,000 blacks in 1990. Socioeconomic data for these cities are obtained from Summary Tape File 3C of the 1990 census. Segregation indices for cities are derived using tract-level data from Summary Tape File 1A. Data on black political representation within cities are manually entered from publications of the Joint Center for Political Studies (1989) and Carpenter 1992. Since race-disaggregated arrest data for central cities are not available on publicly released Uniform Crime Report (UCR) periodicals, we obtained them through a special tabulation provided to us by the Federal Bureau of Investigation. We derive black homicide and robbery arrest rates for 1990 by first averaging the city-level arrest counts over a three year period — 1989, 1990, 1991 — to minimize any year-to-year fluctuations in serious crime. We then divide that average by the total city population aged 10 and older. We exclude those aged 0-9 for two reasons. First, children in this age group are unlikely to be a part of the arrest statistics for homicide and robbery. Second, since the 0-9 age group comprises a substantial part of the U.S. population, any variation across cities in the relative size of that group could potentially bias the results. Finally, because these rates are heavily skewed, we transform them to their natural log in order to induce normality and to avoid heteroskedasticity.[3]

Official data have been criticized on the grounds that they measure the reaction of law enforcement agencies rather than criminal behavior itself. However, for very serious crimes such as homicide and robbery, UCR arrest data appear to reflect accurately the rates of black and white offending (Hindelang 1978; Laub et al. 1987). Seriousness of the crime is the strongest predictor of arrest (Black & Reiss 1970; Gottfredson & Gottfredson 1980; Gove, Hughes & Geerken 1985). Crime severity accounts for the greatest variance in whether a crime becomes officially recorded (Gove, Hughes & Geerken 1985). Based on a comparison of victimization data from the National Crime Survey and arrest data from the UCR, Hindelang (1978) concludes that there is little or no race-bias in robbery arrests. LaFree, Drass and O'Day (1992) compare arrest rates with total crimes known to the police for the years 1957-88 and find correlations of .98 and .97 for robbery and murder, respectively. Hence the available evidence indicates that homicide and robbery arrest rates accurately reflect offending in the total population and among blacks and whites. In the multivariate analysis, we predict these violence rates using ordinary least squares regression models.

SEGREGATION: BLACK ISOLATION FROM WHITES

Isolation refers to the degree of potential contact between minority and majority members across geographic subareas of a spatial unit. Specifically, we focus on *black isolation* (P) from whites within a city. We measure black isolation using Lieberson's (1981) interaction index, which reflects the probability, ${}_bP^*_w$, that a randomly drawn black in the city interacts with a white: This is defined as

$$ {}_bP^*_w = \sum_i \beta_i(w_i/t_i) $$

where B_i is the proportion of all blacks in the city that are located in tract *i*, and w_i and t_i are the number of whites and total population, respectively, in tract *i*. Values range from 0 to 1.0; the former indicating complete spatial isolation of blacks from whites, and the latter reflecting certainty that a given black shares a tract with whites. Massey and Denton (1988b) demonstrate that ${}_bP^*_w$ is the preferred measure of interracial exposure because it loads highly on a single dimension in a factor analysis and has a straightforward interpretation. So as to avoid switching back and forth between the term *isolation* and *interaction*, we reverse the sign of ${}_bP^*_w$ so that we may consistently refer to this as a measure of isolation.

Given the reliance of previous segregation-crime research on unevenness as a measure of segregation, we include an indicator of it in our models. *Unevenness* (*D*) refers to the difference between two groups in their geographic distribution across areal units. For instance, segregation exists if blacks are located in relatively few areas of a city and whites exhibit a comparatively uniform spatial distribution. Typically calculated using the index of dissimilarity, unevenness is defined as:

$$D = [(1/2)\,|B_i - W_i|] * 100$$

where B_i refers to the proportion of all blacks in the city who live in tract *i*, while W_i has a similar meaning for whites. *D* varies from 0 to 100 and is interpreted as the proportion of minority residents that would have to change tracts to produce a uniform race distribution across the city (Shryock & Siegal 1976).

MEASUREMENT OF INDEPENDENT VARIABLES

In our theoretical discussion, we identify three process — economic, cultural, and political — through which black isolation could potentially raise the rates of black violence. Accordingly, we group the independent variables into the same three categories, plus a fourth for standard controls. We recognize that individual predictors may reflect overlapping processes because economic variables, for instance, might be related to cultural responses and/or political conditions and vice versa. However, if the relationship between black isolation and black violence operates via economic, cultural, and political factors, then including indicators of these in our models should weaken the link, if any, between black isolation and black violence.

We include three predictors that reflect black socioeconomic status in central cities. The first is the rate of *black employment*, measured as the proportion of all working-age blacks (16-64) in the city that are employed. Calculating our measure of black employment from only those in the labor force can overestimate black employment since many blacks exit the labor force as discouraged workers (Wetzel 1995). Evidence shows that joblessness increases black violence both directly (Allan & Steffensmeier 1987; Devine, Sheley & Smith 1988; Shihadeh & Ousey 1996) and indirectly as well (Sampson 1987; Shihadeh & Steffensmeier 1994). Second, we include *black poverty*, the proportion of black residents in the central city whose 1989 income fell below the poverty line. As

an indicator of home equity, we measure *black renters* as the proportion of black residents who rent rather than own their residence.

Two variables that measure potential differences in culture are *black youth attachment* and *female-headed households*. The first is the proportion of black teens aged 16 to 19 that are unemployed or not in the labor force, not in school, not in the armed services, and have no high school degree. These are individuals that have either no attachment or weak attachment to major social institutions such as the labor market, armed services, high school, as well as vocational or other secondary educational institutions. In the objectively harsh environments within many black urban areas — where the rates of joblessness, and persistent and intergenerational poverty are high and where legitimate opportunities are lacking but welfare use is common — a widespread sense of cynicism and frustration may make it difficult for the community to cultivate allegiance to mainstream goals. Should the residents of these communities view the returns to education as poor and the prospects of adequate and meaningful employment as slim, mainstream goals such as securing a high school degree or postsecondary degree or certificate as well as looking for or getting a job may not hold the same priority. In other words, the simultaneous combination of a youth aged 16 to 19 being jobless or not in the labor force, without a diploma, not currently enrolled in school, and not in the armed forces strongly suggests a marginalization or detachment from a normative social order. This detachment is of particular concern among those aged 16 to 19 since they are within the crime-prone age group for serious violence.

The extensive discussion about the racial differences in the rates of female-headed households suggests that high rates of female-headed households in black communities are due to economic factors: High rates of black male joblessness have reduced the economic incentives to marriage for black women, elevating the rates of black female-headed households (Wilson 1987). But equally compelling is the suggestion that the source of racial differences in household structure are cultural in nature: Because of historical circumstances and contemporary structural arrangements, black women are more likely to choose female-headed households as the preferred living arrangement. This may be a cultural difference visible more than a century ago (Cherlin 1992; Gutman 1976; Morgan et al 1990; Sudarkasa 1981). But as our earlier discussion of Anderson's (1990) ethnographic research suggests, normative adaptations to the social isolation of the ghetto may exacerbate the racial differences in family structure. To recall, he finds that a contributing factor to the high rates of mother-only families in ghetto areas is an inversion of mainstream values regarding childbearing. In the absence of economically viable males, ghetto women view having a child as a conduit to recognition and social prestige among peers — the entry into the "baby club," as he terms it. Although the economic marginalization of black males is a distal cause, the normative adaptation among black ghetto women is a proximate one. Thus, although there may be economic causes and consequences of the high rates of black female-headed households, from a different vantage point there is strong cultural dimension as well.

Our political variable, *black empowerment,* is the proportion of all city council members that are black (mayors included), divided by the proportion of the city's voting age population that is black. This measure has been used in prior research as an indicator of black political power relative to black voting potential within city units (Browning, Marshall & Tabb 1984; LaVeist 1992). If the ratio is less than one, then the African-American community is considered politically underrepresented in the center city, while a ratio above one means it is empowered. We also estimated our models using a measure of the per capita number of black council members per black voting age resident (correlated .478 with black empowerment). However, we do not report this in the tables since the results are nearly identical to those using the first political measure.

We select control variables on both theoretical grounds and because of their use in earlier research. *Black education* is the proportion of black residents 25 years old and older that have completed high school. *Population size* (natural log transformed) reflects variations in the size of cities in our sample, while the proportion of *black males aged 15-34* controls for age structure. Also, given the regional differences in crime rates (Curtis 1975; Huff-Corzine, Corzine & Moore 1986; Liska & Chamlin 1984), we add a control for whether the city is located in the *North* — i.e., outside the southern region. Since disorder and decline may be related to crime (see Skogan 1992), we control for the degree of abandonment and deterioration by including the proportion of all households that are vacant (*vacant households*).

Because multicollinearity is potentially a problem in macrolevel studies, we examine the issue in a number of ways. First, we do not incorporate variables in our models if the correlations with other independent variables are high enough to warrant concern (≥ 0.80). Second, none of the variance inflation factors (VIF) associated with the parameter estimates in our models raised a concern about multicollinearity.[4] However, since multicollinearity cannot be defined solely in terms of the correlations between independent variables, we also probed for multicollinearity while taking the dependent variables (violence rates) into account. Specifically, we found that the parameter estimates for segregation did not change appreciably when removing or including selected predictors. Also, all significant parameter estimates in our models remained virtually the same when we randomly omitted 10% of the cases and reestimated the model (see Maddela 1992).

BLACK ISOLATION VERSUS UNEVENNESS: A SIMULATION

Before analyzing real data for cities in the U.S., we attempt to clarify the distinction between *black isolation from whites* (*P*), the dimension of segregation used in this analysis, and black-white spatial *unevenness* (*D*), the dimension used in previous segregation-crime research. Both *P* and *D* produce the same results in extreme cases of segregation. When blacks and whites in a city live totally apart or, conversely, are completely integrated, *P* and *D* give similar results. But when the degree of black-white residential segregation lies in between these two extremes — and in reality it does — *P* and *D* tell different stories. To clarify this we simulate the geographic distribution of residents in two hypothetical cities depicted in Figure 1.

FIGURE 1: Two Hypothetical Cities Containing Black and White Residents

City 1

Blacks =	5,000	2,500	2,500	0	
Whites =	0	2,500	2,500	5,000	
Percent blacks in each tract =	100%	50%	50%	0%	P = .75, D = 50%

City 2

Blacks =	3,750	3,750	1,250	1,250	
Whites =	1,250	1,250	3,750	3,750	
Percent blacks in each tract =	75%	75%	25%	25%	P = .58, D = 50%

Each city contains just four tracts, and each tract contains some combination of blacks and whites for a total of 5,000 people (we limit our simulation to four tracts for ease of interpretation). The results indicate that both cities have exactly the same level of unevenness in the spatial distribution of blacks versus whites ($D = 50\%$). In either city, exactly half the population of blacks or whites would have to relocate to a different tract in order to achieve an even black-white spatial distribution. However, the degree of black isolation (P) is substantially different between the two cities. Black isolation from whites in city 1 is quite high ($P = .75$), whereas in city 2 it is lower ($P = .58$). This difference is due to the manner in which blacks and whites are distributed across the tracts. City 1 has a tract containing 100% blacks and another containing 0% blacks. In both of these tracts, black isolation is extreme since the chance that blacks will interact with whites is zero. Thus half the tracts in city 1 contain black populations completely isolated from whites, and so overall black isolation in the city is high. On the other hand, *all* the tracts in city 2 contain at least some residents of either race, and thus the degree of black isolation is reduced.

In the real world the two forms of segregation would shade into one another. But this brief simulation shows that segregation in the form of black isolation from whites is distinct, and can vary independently from the more widely used dimension, unevenness. Rather than employing unevenness as the generic form of segregation, we can enhance our understanding about the link between segregation and serious crime by more precisely matching our theoretical arguments to specific distributional forms of segregation.

Results

In Table 1 we provide descriptive statistics for the variables used in our models. Although we analyze only black crime in the multivariate analysis, some descriptive statistics for whites are provided for comparative purposes. Three findings stand out. The most notable feature of Table 1 is the substantial race-gap in the rates of urban violence. The average rate of black homicide and robbery are, respectively, 54.6 and 460.3 per 100,000 population, whereas the corresponding rates for whites are 22.6 and 184.9. These major racial differences in the rates of serious violence are consistent with previous findings and point to the need to racially disaggregate ecological models of violent crime.

A second feature in the findings of Table 1 is the degree of black-white segregation in U.S. cities. In terms of black isolation, the mean probability that a randomly chosen black will be isolated from whites (P) is .56. However, there appears to be high degree of variability in the level of black isolation across our sample of cities (std. dev. = .20). We observed that about one quarter of cities (37) exhibited P values of .75 or greater, suggesting an extreme level of black isolation in a substantial number of urban areas. There also appears to be a considerable amount of unevenness (D) in the residential distribution of urban blacks and whites. The mean index of dissimilarity is 54.3, suggesting that on average over one-half of black residents in center cities would have to relocate in order to create an even residential distribution of blacks and whites.

Table 1 also illustrates the racial differences in urban socioeconomic conditions. Most revealing of the economic and social hardship in urban black communities are the high rates of black poverty. Nearly 30% of black residents (.29) are below the poverty line compared to just over 10% of whites (.11). Indeed, more detailed descriptives of our city data reveal that no city in our sample had a white poverty rate above the mean black poverty rate for all cities. Blacks in our sample also had lower rates of employment compared to whites (.57 vs. .62). Blacks also show four times the white proportion of young, unemployed dropouts (black youth attachment). About 11% of black youths aged 16-19 — or one of every nine — are unemployed, not in school, lack a high school degree, and are not in the armed forces, versus only 4% among whites. Finally, the results reveal the tendency among blacks toward nontraditional family structures. Nearly a third of black households are headed by a female (.31), compared to less than one-tenth among white households (.09).

Overall, these descriptive findings attest to racial differences in the social conditions of blacks versus whites in U.S. cities. In particular, both rates of black poverty and female-headed households are exceedingly high. Likewise, the residents of these communities are restricted to areas with low white populations, increasing the isolation of blacks from whites. The results also confirm the disproportionately high rates of black violence in U.S. cities. The rates of homicide and robbery are several magnitudes higher among blacks than among whites.

TABLE 1: Descriptive Statistics of City-level Structural Variables for Blacks in Major U.S. Cities in 1990

	Mean	Std. Dev.
Black homicide rate (per 100,000)[a]	54.6 (22.8)[b]	157.6 (64.6)
Black robbery rate[a]	460.3 (184.9)	1,650. 2 (805. 2)
D - Uneveness in spatial distribution	54.3	17.1
P - Black-white isolation[a]	.56	.20
Population size	380,275	704,737
Proportion black	.24	.17
Black males aged 15-34	.09	.20
North	.49	.50
Vacant households	.09	.03

BLACK-WHITE RESIDENTIAL SEGREGATION AND BLACK VIOLENCE RATES

Table 2 provides the ordinary least squares (OLS) estimates for six models, the first four of which contain a reduced set of predictors. Models 1 and 2 predict black homicide and robbery using only one measure of segregation, unevenness (*D*). Consistent with previous findings, unevenness in the spatial distribution of blacks and whites has a significant positive relationship to both black homicide (.016) and black robbery (.012). As expected, homicide rates are positively related to city size (.966) and to the proportion of black males aged 15-34 (.739). Model 2, which predicts black robbery rates, yields a similar pattern of findings.

The results of models 1 and 2 are consistent with previous research showing that rates of violence are linked to segregation — when segregation is viewed as an *unevenness* (*D*) in the spatial distribution of blacks to whites. However, models 3 and 4 suggest that this relationship may be due to an underlying association between black violence and *black isolation* (*P*) from whites. Model 3 shows that as black isolation increases, so does the black homicide rate (1.145). Likewise in model 4, black isolation is significantly and positively related to black robbery rates (.827). The standardized estimates suggest that in comparison to other variables in the models, black isolation stands out as a major influence of black violence. The effect of black isolation on black homicide is $b = .415$, suggesting that a one-standard-deviation rise in black-white isolation is associated with nearly a one-half standard deviation rise in black homicide, while a similar rise in isolation is associated with more than a one-third standard deviation rise in black robbery (.346). But of particular note is that controlling for black isolation (models 3 and 4) eliminates the effect of unevenness (*D*). Although previous segregation-crime research has focused on unevenness as a predictor of crime, our results imply that a spatial unevenness in the distribution of blacks to whites does not, in itself, engender black violence. The more predictive dimension of segregation appears to be black isolation from whites.

To the extent that black isolation influences black rates of violence is mediated via economic, cultural, and political spheres within black communities, then controlling for these characteristics should decrease the association between black isolation and black violence. Models 5 and 6 predict black homicide and robbery using socioeconomic, cultural, and political variables. *Socioeconomic* variables include black employment, black poverty, and black renters; *cultural* variables include black youth attachment, black female-headed households; and *political* variables include black political empowerment. We observe that the effect of black isolation on serious violence is reduced upon inclusion of these measures. This is particularly evident when comparing the standardized coefficients in models predicting black homicide. In the reduced model (3), the effect of black isolation on homicide is larger ($\beta = .415$) than in the full model ($\beta = .307$). Similarly, the effect of black isolation on robbery ($\beta = .352$) is reduced upon the inclusion of these mediating characteristics ($\beta = .322$).

Of the three sets of variables, those reflecting economic and cultural characteristics stand out as significant. Model 5 of Table 2 shows that black employment is negatively related to the rate of black homicide ($\beta = -.118$). That

is, as black employment rises, black homicide falls. But both our cultural indicators — black youth attachment and black female-headed households — are also significant predictors. Increases in the proportion of unattached black youth (β = .095) or in the proportion of black households that are headed by a female (β = .123) are accompanied by increases in the rates of black murder. Model 6 also reveals the importance of economics, given that proportion of blacks that are poor (β = .180) or that rent housing (β = .061) are positively related to black robbery, and culture, as suggested by positive relationship between black female-headed households (β = .247) and black robbery.

Yet the effect of black isolation on violence remains significant despite controlling for these features of black urban communities. There may be a number of reasons for this. First, despite efforts to control for economic, cultural and political structures in black urban communities, there are limitations in the kinds of data available to macro researchers of crime (and of other substantive areas) and in the validity of available measures. Second, as suggested in the theoretical discussion, segregation implies not merely the spatial concentration of a group, but also any negative characteristics associated with that group. Thus, a critical feature of social isolation is not just the overall levels of unemployment, youth attachment, etc., but also in how it spatially distributes these characteristics within a city.

Nonetheless, Table 2 offers several important findings. First, black isolation is a robust predictor of black violence, supporting the view that segregation elevates black violence by spatially and socially isolating black communities.

Second, previous findings of a link between black-white spatial unevenness (*D*) and black violence appear to be due to an underlying association between black isolation and black violence. Once black isolation is controlled, black violence does not appear to be related to the more typical conceptualization of segregation — spatial unevenness between blacks and whites. Third, the isolation-violence link is partly accounted for by economic and cultural indicators, suggesting that the social isolation of blacks produces economic and normative responses that are conducive to high rates of serious violence.

UNEVENNESS AND BLACK ISOLATION

Although black isolation from whites appears to be a strong predictor of black violence, the degree of independence between the two segregation measures requires closer examination. The correlation between unevenness (*D*) and black isolation (*P*) is substantial (.76, unreported), which raises a concern about the independent effect of black isolation on black violence. In other words, although unevenness and black isolation are potentially independent of one another, to what extent is the effect of black isolation (*P*) on violent crime independent of the underlying level of unevenness (*D*)? If the observed relationship between black isolation (*P*) and crime is significant in cities with low *D* values, as well as in cities with high *D* values, this would strengthen our inference that black isolation has crime-producing effects that are independent of the more commonly used measure of segregation.

+ $p < .10$ * $p \leq .05$

To explore these issues in greater detail, we estimate models that predict the effect of black isolation on black homicide and robbery *at two levels of unevenness.* Cities with *D* values of 59 or less are grouped into a "low/medium-D" category, while cities with *D* values of 60 and over are grouped into a "high-D" category. These cutoff points were chosen for two reasons. First, this categorization is consistent with Massey and Denton's (1993) usage where cities with segregation indices of 60 and over are regarded as "hypersegregated." Second, this dichotomization occurs at the near-median point in the sample, resulting in a roughly equal number of cities in each group (low-medium *D*, *N* = 80; High *D*, *N* = 71). Thus, comparisons between models with high-*D* and low/medium-*D* cities are not confounded by major differences in subsample size.

Table 3 presents the results of four models predicting black homicide and robbery for both types of cities. The evidence suggests that the relationship between black isolation and black violence is substantial at both levels of unevenness. For instance, the standardized parameter estimate of black isolation on black homicide in low/medium-*D* cities is .288 (model 1), while in high-*D* cities it is .302 (model 3). This suggests that black isolation has a major influence even in cities with low to moderate levels of black-white unevenness. Indeed, the effect of black isolation on robbery is greater in low/medium-*D* cities (.403, model 2) than in high-*D* cities (.138, model 4).[5] Overall, the fact that black isolation was a significant predictor in both medium/low-*D* and high-*D* cities, strengthens our confidence regarding an independent effect of black isolation on

the city rates of black homicide and robbery. Segregation, in the form of a physical and social isolation of blacks from whites in urban areas is associated with high rates of violence in urban black communities.

Summary and Discussion

We extend the research on segregation and crime by addressing three key limitations of extant research in this area. First, prior conceptualizations about segregation and crime are drawn from the widely known literature regarding inequality and crime, obscuring the potentially more relevant issue of black social isolation. Second, previous research relies on indicators that conceptualize residential segregation as a spatial unevenness (*D*) in the distribution of blacks to whites, neglecting the theoretically critical dimension of black isolation (*P*) from whites. Third, the bulk of previous studies have not examined how segregation directly effects black violence, despite the fact that both segregation and its consequences are problems faced mainly by urban black communities. Building on recent research on the rise of the urban underclass, we examine whether reductions in the potential for race contact, black isolation, leads to high rates of urban black homicide and robbery.

Our results reveal that segregation is a major predictor of the rates of homicide and robbery among blacks. Consistent with prior research, spatial unevenness (*D*) is positively associated with serious black violence at the city level. However, when black isolation (*P*) is incorporated into our models of serious black crime, the effect of unevenness becomes negligible. Instead, the results reveal that in cities when blacks are isolated from whites (i.e., black isolation), the rates of serious black violence are exceedingly high. Several potential mediators of this effect include the black rates of unemployment, poverty, youth institutional attachment, and female-headed households. However, since these factors accounted for only about 25% of the empirical association between black isolation and black homicide, future research needs to identify additional factors that mediate the link between isolation and violence. Our findings also show that the effect of black isolation on serious violence is substantial even in cities in which the underlying level of unevenness (*D*) is medium/low.

We derive a number of implications from these findings. First, the results support the view that black social isolation has profoundly negative consequences. Secluded in their own communities, many urban blacks lack the sustained contact with mainstream institutions necessary for upward social and economic mobility. Black isolation may lead to weakened labor force attachment and thereby deprive residents of the main conduit by which adults prove their worth in the larger society. In extreme cases it can create an environment which fosters a self-image based on violence and reinforce a variety of behaviors that increase the social disability of blacks. Black isolation can also divest black urban communities of the advantages of pluralist politics and makes them vulnerable to economic downturns and government cutbacks. The combination of these and other negative consequences of black isolation, exacerbates the disinvestment

and decline of many black communities in major cities of the U.S. and contributes to the rise of black predatory crime.

Second, researchers should recognize that blacks and other minorities can be segregated in a variety of ways. Broadening our view of residential segregation will lead us to consider alternative — and perhaps more appropriate — causal mechanisms by which segregation leads to crime. Of particular concern, is the heavy reliance on unevenness as an indicator of black-white residential segregation and as a predictor of violence. In light of our findings, this practice appears to be unwarranted. Indeed, we suspect that previous evidence of a significant relationship between violence and segregation — as measured by unevenness (*D*) — actually reflects the underlying relationship between black violence and black isolation. To understand how the spatial distribution of blacks relative to whites generates violence and other indicators of social malaise, sociologists need to examine the theoretical mechanisms implied in each of the various forms of residential segregation. For instance, another distributional form of segregation identified by Massey and Denton (1988b) is "centralization." This refers to the degree to which minority groups reside close to the center of a city. A research tradition descended from the Chicago school (cf. McKenzie 1933; Park & Burgess 1925; Wirth 1928) documents how the abundance of low-skill jobs contributed to the social mobility of successive waves of immigrants. But recently there has been a growing concern about the

+ $p < .10$ * $p < .05$

structural disadvantages inner-city life, which include a shrinking low-skill job-base, the depletion of the city's tax base as wealthy residents move to the suburbs, and a host of other factors that reduce the economic and social opportunities of inner-city residents (Blackley 1990; Cain & Finnie 1990; Hawley 1950; Kasarda 1990). In a broader sense, the structural disadvantages specific to inner-city life may contribute to the economic decline of minority communities in center cities and erode their capacity to restrain violent behavior.

Finally, we suggest several avenues for future research that build on the present analysis. First, although the objective of the present analysis was to examine whether a cross-sectional relationship exists between social isolation and violence, we would like to see this work extended using a longitudinal design. Massey and Denton (1993) demonstrate that black isolation increased steadily after the turn of the century. Although this implies that such a study would use data for many decades, it is likely to be truncated given the poor and incomplete UCR data that exist prior to 1960. Second, Wilson (1993) points out that social isolation results not only from a lack of contact between the races, but between the classes as well. Particularly informative would be studies examining whether the social isolation of low-income blacks from medium/high-income blacks in urban areas has a crime-producing effect in black communities. Third, while previous studies examine whether the spatial distribution of *people* impacts on serious crime, an important though neglected question concerns how the spatial distribution of socioeconomic *characteristics* influences crime. Underlying the

relationship between segregation and crime is not merely the spatial isolation of blacks, but the geographic concentration of negative characteristics that are collinear with the urban black experience, such as poverty, joblessness, low job-skills, low education, welfare, teen pregnancy, and family disruption. Such studies would refine our understanding about how the spatial segregation of U.S. blacks, unique in its degree and persistence, leads to lethal violence and other predatory behavior.

Notes

1. Massey and Denton (1988) identify five distinct forms of segregation. (1) *Unevenness,* which refers to the distribution of minority and majority groups relative to one another across spatial units of a city. (2) *Isolation,* a concept referring to the degree to which minority group members come into contact with only other minority group members. (3) *Centralization* measures the degree to which a minority group is spatially located in the center of an urban area. (4) *Concentration* reflects the amount of physical space a minority group occupies in an urban area. A highly concentrated group resides in a relatively small area. (5) *Clustering* refers to a residential pattern in which spatial units occupied by minority groups are contiguous to each other. High clustering resembles an enclave, while low clustering resembles a checkerboard pattern.

2. In Peterson and Krivo's (1993) important analysis of segregation and crime, social isolation is noted as a possible mechanism by which segregation increases crime (p. 1005). However, the authors measure segregation using both the Index of Dissimilarity and ETA. But since Massey and Denton (1988) show in unambiguous terms that both of these measures reflect the same thing — unevenness in spatial distribution, a direct measure of black-white social isolation is not used. Potter (1991) did use a black-white isolation measure, but his analysis cannot readily be grouped with the other segregation-crime studies for several reasons. First, it is a demographic analysis (published in *Demography*) that focuses mainly on black-white differences in life expectancies. Second, the empirical and theoretical relationship between segregation and crime is not explored. Third, standard independent and control variables in criminology are not included in the analysis. Fourth, the impact of segregation on *black* crime is not examined.

3. While the diagnostic statistics justified this transformation, we also estimated our models using crime rates that were not log-transformed. The results did not differ substantially. Sampson (1987) and Shihadeh and Steffensmeier (1994) also multiplied the arrest rates by the ratio of offense to arrest in each city in order to account for possible jurisdictional biases in the probability of arrest across cities. However, we conclude that such an adjustment is unnecessary and does not meaningfully alter the results. We are not surprised that adjusting the data makes little differences since the correlation between adjusted and unadjusted violence rates is over .90.

4. None of the variance inflation factors (VIF) associated with the parameter estimates exceeded a value of 4. The values ranged from 1.16 to 3.24.

5. To examine whether these results are sensitive to the specific dichotomy chosen, we estimated models at a variety of cutoff points of D. The extended analysis showed that the association between P and crime was significant when we varied the cutoff points of D values from 48 to 68. Samples of cities with D values lower than 48 or higher than 68 were excessively small, which seriously reduced our degrees of freedom (e.g., $D < 48$, $N \leq 37$; $D > 68$, $N = 28$). Also, although the results in Table 3 suggest that the association between P and crime is greater in low/medium cities than in high-D cities, further analysis shows that this difference is not significant. We estimated several models that contained a multiplicative interaction term between D and P. In some models we maintained D as a continuous variable, both in the main effect and interaction term, while in others we dichotomized D into the two categories listed in Table 3. In each case the interaction term was not significant, suggesting that the effect of P on crime does not change at either level of D.

Perceived Risk versus Fear of Crime: Empirical Evidence of Conceptually Distinct Reactions in Survey Data*

PAMELA WILCOX ROUNTREE, *University of Kentucky*
KENNETH C. LAND, *Duke University*

Abstract

The conceptualization and measurement of fear of crime have received considerable attention in the research literature. Nevertheless, most sample surveys use indicators that only tap a general, cognitive assessment of safety — assumed to represent fear of violence. This article examines whether there are conceptually and empirically distinct dimensions of fear of crime by comparing the micro- and macrolevel antecedents of such a general, cognitive "fear" — which we call "perceived risk" — with those for a more emotionally based, burglary-specific fear. Hierarchical logistic regression models for both types of fear are presented. Some similarities were found between fear and risk in terms of various predictors, but results generally provide further empirical evidence that the two constructs are quite distinct. At the individual-level, the effect of gender is different across models, and routine-activities variables are somewhat better predictors of burglary-specific fear in comparison to risk perception. At the contextual level, neighborhood integration serves to diminish respondents' perceptions of neighborhood danger, yet this variable is positively related to burglary-specific fear.

Previous research on fear of crime suggests that there is ambiguity in defining and measuring fear. Different studies of fear use different operational measures, illustrating a lack of consensus on what "fear of crime" actually means (see Ferraro & LaGrange 1987 for a review of fear of crime studies and their respective measures; also see Bursik & Grasmick 1993). Some measures stem from survey questions such as "How safe is your neighborhood from crime?" and "How safe do you feel walking alone in your neighborhood at night/during the day?" In these questions, respondents are asked to make judgments about risk while in questions such as "How afraid are you of becoming a victim of rape/robbery/murder, etc.?" they are asked to make more personal statements of emotionally based concern about crime. Yet, when scholars discuss fear of crime using any of these different types of measures,

** We would like to thank Terance D. Miethe for providing the survey data analyzed herein.  Social Forces, June 1996, 74(4):1353-1376

often no attempt is made to specify the type of fear or the type of crime under question. "Fear of crime," then, ranges from general, cognitive perceptions of safety in one's neighborhood to affective, personal, emotional reactions to the possibility of being victimized by a specific type of crime (Ferraro & LaGrange 1987).

Given the range of possibilities, concerning fear of crime, it is quite conceivable that the causes of this fear vary, depending upon the types of perceptions or reactions under consideration. Nonetheless, very few studies have attempted to address these potential distinctions. The review of the literature on fear of crime by Ferraro and LaGrange (1987) indicates that a large percentage of studies use only one indicator of fear — usually a more general, cerebral assessment of community safety for tapping fear rather than a personal reaction to a specific type of victimization. Indeed, Ferraro and LaGrange (1987), using a definition of fear of crime that "refers to the negative emotional reactions generated by crime or symbols associated with crime" (73), claim that the often-used general, cognitive measures refer to "judgments of risk," not actual fear. Thus, recent attention to the measurement of fear has underscored a conceptual distinction between commonly used general, cognitive "fear" — or risk perception — and crime-specific, emotionally based fear.

However, the literature is limited in terms of explicit and comprehensive examination of potential distinctions regarding covariates of different measures of the fear of crime. The present study, while assuming the Ferraro and LaGrange (1987) definition of fear — "the negative emotional reaction generated by crime or symbols of crime" (73) — extends previous work by integrating micro- and macropredictors in examining the differences between personal, burglary-specific fear of crime and a measure of risk perception resembling a conceptualization and operationalization of fear employed in most extant research.

Previous Research: Correlates of Fear of Crime

As mentioned above, most research on the fear of crime focuses on a cognitive or judgment-based, general concern that may better be termed *risk perception*. We used survey items such as "Do you think that people in this neighborhood are safe inside their homes at night/during the daytime?" or the previously mentioned, "How safe is your neighborhood from crime?" are commonly used. These items elicit general assessments of safety from the respondents rather than personal, more emotional experiences (Ferraro & LaGrange 1987). In support of the purported conceptual distinction of this type of measure from actual fear, others have speculated that fear of crime, when measured in this general sense, may refer to perceptions of urban disorder rather than actual fear of crime per se (e.g., Bursik & Grasmick 1993; Garofalo & Laub 1979; Wilson & Kelling 1982).

Many of the earlier studies of this judgment-based, general type of fear (or risk perception) focused on sociodemographic correlates, finding, for example, that fear was directly related to age and gender. Typically, these studies found that women are more fearful and that fear increases with age (e.g., Baumer

1979; Clarke & Lewis 1982; Garofalo 1979). These sociodemographic correlates are presumably related to physical or social vulnerability. More recent research on the sociodemographic correlates has focused on, for example, interactions between age, race, and sex, indicating that the effects of sociodemographic characteristics on fear may be other than simply additive (Baumer 1985; Ortega & Myles 1987).

Research on the relationship between fear of crime and information about crime — through direct or indirect victimization, or through media accounts — has also been prevalent. Despite the fact that prior victimization is generally considered a relatively weak predictor of fear, work by Skogan and Maxfield (1981) indicated that previous victims are more fearful than their nonvictimized counterparts. Skogan and Maxfield also found significant effects on fear for indirect victimization — referring to knowledge of crime or victimization experiences of family, friends, and neighbors via interpersonal communication. Other research indicates that initial media reports of serious local crimes can increase levels of fear (e.g., Liska & Baccaglini 1990). Further individual-level variables found to affect fear in the literature include social-psychological characteristics such as locus of control and self-image (van der Wurff, van Staalduinen & Stringer 1989) and lifestyle or routine-activity attributes such as exposure (Stafford & Galle 1984).

Extant research on the fear of crime has also emphasized the contextual (city- or neighborhood-level) factors involved in explaining fear. Macrolevel studies indicate that structural features such as physical and social incivility, poor social integration, segregation, population size, and community-level crime increase levels of fear among residents (Lewis & Maxfield 1980; Lewis & Salem 1986; Liska, Lawrence & Sanchirico 1982; Liska & Warner 1991; Skogan & Maxfield 1981; Taylor, Gottfredson & Brower 1984; Taylor & Hale 1986).

Risk Perception versus Offense-Specific Fear of Crime

As alluded to earlier, the extant research on the fear of crime has generally ignored the potentially important distinctions between types or dimensions of fear of crime. While most researchers recognize that fear of crime can have a multitude of meanings, the studies that have been done focus on a general, judgment-based measure for fear and assume that fear of violent crime is being tapped. Research efforts by Warr and Stafford (1983), Warr (1987), LaGrange, Ferraro, and Supancic (1992), and Ferraro (1995) represent the few exceptions to this trend and support the notion of a conceptual distinction between judgments of risk and actual fear. Warr and colleagues have examined the proximate causes of fear for up to sixteen different offense categories and have found that, although risk perception ("how likely is ____ to happen to you in the next year?") is often an important predictor of fear ("how afraid are you of becoming a victim of ____?"), it is not perfectly correlated with fear, since fear also depends upon individual-level perceived seriousness of the offense in question and an individual's risk sensitivity (Warr 1987; Warr & Stafford 1983). In a study of the contextual predictors of fear, LaGrange, Ferraro, and Supancic (1992) found that neighborhood incivilities — commonly found predictors of

"fear" in the extant research reviewed above — were more strongly related to perceived risk than they were related to actually being afraid. LaGrange and associates (1992) also found perceived risk to be an important predictor of actual fear, thereby further supporting the need to disambiguate between fear and judgments of risk. That is, assuming that measures of judgments of risk also measure fear of crime "is both invalid and obscures the processes that generate these perceptions" (Ferraro & LaGrange 1987:73).

In all these studies, then, perceived risk is shown to be one of several important components in explaining fear. Though such findings support the notion of a conceptual distinction between perceived risk and actual fear as posited by Ferraro and LaGrange (1987), none of the studies gives explicit attention to this matter in any comprehensive empirical way. A recent study by Ferraro (1995) deals with this issue somewhat more explicitly and finds evidence of conceptual distinction, yet uses a limited array of contextual and individual-level variables. Thus, the present study tests the ideas of Ferraro and LaGrange (1987) and extends the empirical evidence of others (Warr & Stafford 1983; Warr 1987; LaGrange, Ferraro & Supancic 1992; Ferraro 1995) while examining differences in empirical results between judgment-based risk perception and more personal, emotionally based burglary-specific fear. In particular, we seek to uncover and understand distinctions in the significance of individual-level predictors as well as in direct and moderating effects of social context regarding risk perception as opposed to a specific concern for burglary victimization.

Methods

In order to address these potential distinctions, we employ a hierarchical logistic regression modeling procedure using the ML3E software (Prosser, Rasbash & Goldstein 1991a, 1991b). The hierarchical modeling approach, growing out of Bayesian estimation in statistics (Lindley & Smith 1972), sociological contextual-effects research (Mason, Wong & Entwisle 1983), and educational research on growth curves and classroom and school effects (e.g., Goldstein 1987; Raudenbush 1984; Strenio, Weisberg & Bryk 1983), has recently been applied to criminological multilevel research on the antecedents and effects of victimization (Rountree & Land 1996; Rountree, Land & Miethe 1994).

While distinctions between risk perception and burglary-specific fear in terms of multilevel explanatory variables could be studied through conventional linear or logistic models, hierarchical models more appropriately account for the implicit hierarchy and structure of data. Simply including contextual variables in conventional linear or logistic regression models along with individual-level variables does not account sufficiently for the idea that individuals fall into many socially meaningful groups or categories and that individuals clustered within the same groups are often likely to be more similar regarding certain social characteristics than are individuals grouped differently. For instance, because individuals are distributed nonrandomly across neighborhoods, an assumption of independent error terms is inappropriate when the survey design incorporates individuals clustered within various neighborhoods (Hox & Kreft

1994; Ringdal 1992). Hierarchical linear or logistic regression models account for the implicit hierarchy of data by employing submodels — each of the levels in the structure or hierarchy is represented with its own submodel. These submodels, along with nested error terms, can account for effects and sources of variation at each of the levels of analysis represented in the data (see Bryk & Raudenbush 1992 for a general exposition).

Data and Variables

SAMPLE DESIGN

The primary data source for the analyses presented here is victimization survey data as part of a larger crime research project for Seattle, Washington. The survey data were collected in 1990 on 5,302 individuals clustered within 300 city-block pairs (or neighborhoods) and 100 of the city's stable 121 census tracts (Miethe & McDowall 1993; Miethe & Meier 1994). We deleted cases with missing data, leaving 5,090 individuals for analysis.[1] Three pairs of city blocks were selected from each of the census tracts. One block in each pair contained a street address at which a burglary had been reported in 1989; the other block in each pair bordered the block with the burglary. A sample was then drawn from residents of the three city-block pairs within each tract.

While the city-block pair was the contextual unit of interest in the original study, here we are interested in both the city-block pair, or *neighborhood*, and the *census tract*. The fact that one of our contextual variables of interest — official neighborhood burglary rates — was unavailable at units smaller than the census tract primarily guided our decision to include the tract as a contextual unit. Due to the clustering at the neighborhood level in the sample design, however, ignoring neighborhoods as a contextual unit would undermine results if, as is highly possible, households in the same neighborhood within a given tract are more similar to one another than they are to other households in the same tract yet not within the same immediate neighborhood.

Within each neighborhood, an average of 18 households were sampled; within each tract, an average of 50 housing units were sampled. A reverse telephone directory was the sampling frame. The resulting sample appears to underrepresent young adults, low-income families, and movers (transient households); home owners and college-educated respondents are overrepresented (Miethe & Meier 1994). Finally, because of the way in which neighborhoods were selected within tracts (on the basis of burglary reports), the sample design also disproportionately stratifies on the basis of burglary victimization.

DEPENDENT VARIABLES

Both perceived crime risk and burglary-specific fear serve as dependent variables for our analyses. *Burglary-specific fear* is indicated by whether or not the respondent worries at least once a week about his/her home being burgled. *Perception of crime/victimization risk,* on the other hand, is indicated by whether

or not the respondent perceives his/her neighborhood to be either somewhat unsafe or very unsafe from crime.[2]

Both of these measures refer to perceptions or emotions specific to the time of the survey. Nearly 39% of sampled respondents were fearful of burglary specifically, while just over 24% indicated a feeling of being unsafe in their neighborhood (see Table 1).

INDIVIDUAL-LEVEL EXPLANATORY VARIABLES

Both individual-level and aggregate-level, contextual indicators are used as independent variables in the analyses. First, individual-level independent variables include sociodemographic characteristics, lifestyle or routine-activity attributes, including factors related to the ecology of crime, and information about crime stemming from previous personal victimization experiences.

Previous burglary victimization is indicated by whether or not the respondent experienced an attempted or completed break-in of his/her current home within the two years *preceding* the survey (in contrast to the contemporaneous nature of the fear measures). Thus, although we use cross-sectional data, it is possible to presume that victimization experiences, in most cases, precede reported levels of fear or risk.

Variables measuring routine-activity risk factors are also included in the analyses. Exposure, indicating how accessible a target is in relation to motivated offenders, is indicated by three different measures. First, the number of nights during the previous week that the home was left unoccupied (*home unoccupied*) reflects this accessibility, especially in terms of household victimization. The number of attractive *access routes* leading into and out of the respondent's home (e.g., presence of ground floor windows, alley behind the home) is also indicative of exposure, as is whether or not the respondent's home is a *corner residence*, as opposed to situated in the middle of a block.[3]

Another routine activity characteristic, target attractiveness, is also measured in several different ways. Target attractiveness — referring to the value the target represents — is measured first by an index tapping the number of expensive, portable household goods within the respondent's home (*expensive goods*), including a portable color television, a VCR, a 35 mm camera, a home computer, and a bicycle or motorcycle. Secondly, *family income* is used as a measure of target attractiveness.[4]

We also include measures of guardianship, or the ability of targets to effectively prevent victimization through the use of other people or objects. First, we use an index representing the number of *safety precautions* employed by the respondent two years prior to the survey, including use of locks on doors, installation of extra locks (e.g., deadbolt locks or chains), use of a light-timer device or leaving lights on, membership in a crime-prevention program, ownership of a burglar alarm or security system, ownership of a dog, ownership of a weapon, or having neighbors watch property when away. Further, we include a measure of the number of *guardianship barriers* associated with the respondent's home, including the presence of a tall fence or hedge and the presence of an empty house or vacant property next door. The more barriers around a respondent's property, the more likely it is that neighbors will be

TABLE 1: Variables, Metrics, and Descriptive Statistics[a]

Variables	Metrics	Descriptive Statistics Mean	Std. Dev.	Range
Dependent variables				
Burglary-specific fear	(O = no, 1 = yes)	.385	.487	0-1
Perceived risk	(O = safe, 1 = unsafe)	.241	.428	0-1
Explanatory variables				
Individual-level characteristics				
Age	(1 = 10-19 . . . 7 = 70 and older)	4.367	1.717	1-7
Gender	(0 = female, 1 = male)	.503	.500	0-1
Race	(0 = white, 1 = nonwhite)	.150	.358	0-1
Home unoccupied	(nights per week)	1.791	1.969	0-7
Expensive goods	(no. of items owned)	2.533	1.408	0-5
Safety precautions	(no. of precautions)	3.837	1.509	0-9
Live alone	(O = no, 1 = yes)	.258	.437	0-1
Family income	(1 = LT $10k . . . 7 = GT $100k)	3.371	1.370	1-7

Contextual characteristics[b]				
Busy places	(no. of places nearby)	3.441	1.340	.82-7.19
Ethnic heterogeneity	(proportion nonwhite * proportion white)	.090	.079	0-.25
Neighborhood incivilities	(no. of indicators)	1.328	.704	0-3.30
Social integration	(no. of indicators)	3.516	.801	1.41-5.35
Burglary rate	([no. reported to police in 1989 and 1990/ households] * 100)	7.463	3.903	1.81-18.52

[a] The total sample size is 5,090 individuals, 300 neighborhoods, and 100 census tracts

[b] Summary statistics for busy places, ethnic heterogeneity, neighborhood incivilities, and social integration are based on the neighborhood block-pair as the unit of analysis; summary statistics for burglary rate are based on the census tract as the unit of analysis.

hindered from providing effective guardianship, thereby indicating low guardianship. A social dimension of guardianship is measured by whether or not the respondent *lives alone.* Sociodemographic variables for *age, race, and gender* are also included as individual-level explanatory variables. We are interested in any differences regarding the explanatory power associated with these individual-level characteristics in understanding risk perception versus burglary-specific fear.

CONTEXTUAL VARIABLES

Several contextual, neighborhood-level attributes are created by aggregating individual responses to certain items pertaining to neighborhood disorder or disorganization within city-block groups. Neighborhood population density or traffic is measured by averaging the number of places for public activity (*busy places*) within the neighborhood block pair as reported by respondents. Busy places include schools, convenience stores, bars, fast-food restaurants, office buildings, parks or playgrounds, shopping malls, hotels/motels, and bus stops. Neighborhood *incivility* is measured by an index averaging the number of problems or signs of disorder (as perceived by individual respondents) within the neighborhood, including the presence of teenagers on the street, litter in the street, abandoned or boarded buildings, poor street lighting, and signs of vandalism (e.g, graffiti). Neighborhood *ethnic heterogeneity* is measured by multiplying the proportion of respondents within each neighborhood block pair who are white and the proportion nonwhite. Neighborhood *social integration* is measured by an index averaging the indicators of cohesion among fellow-residents, including whether or not respondents recognize strangers on their block, have friends or relatives on their block, watch neighbors' property when they are away, borrow items from neighbors, have lunch or dinner with neighbors, and help neighbors with problems.[5]

A final contextual characteristic was created at the census-tract level with Seattle police data. Specifically, a *two-year, tract-specific residential burglary rate* (per 100 households) was calculated for each of the 100 census tracts in the sample by combining official burglary counts for 1989 and 1990 (from police data), dividing by the total number of households (from 1990 census data), and multiplying by 100. As with the individual-level explanatory variables, we seek to discern whether or not the direct and moderating effects of these contextual characteristics are similar in cases of risk perception and burglary-specific fear.

Results for Burglary-Specific Fear

INDIVIDUAL-LEVEL ANALYSES

Given the data and measures described above, an individual-level model as part of an initial random-coefficient regression model for burglary-specific fear (whether or not respondents worry about their homes being broken into at least once a week or more) for individual *i* living in neighborhood *j* and census tract *k* was specified as:

$$\log(p_{ijk}[1-p_{ijk}]^{-1}) = \beta_{0jk} + \beta_{1jk}(age_{ijk}) + \beta_{2jk}(gender_{ijk}) + \beta_{3jk}(race_{ijk}) + \beta_{4jk}(home\ unocc_{ijk}) + \beta_{5jk}(income_{ijk}) + \beta_{6jk}(goods_{ijk}) + \beta_{7jk}(saftey_{ijk}) + \beta_{8jk}(live\ alone_{ijk}) + \beta_{9jk}(barriers_{ijk}) + \beta_{10jk}(access_{ijk}) + \beta_{11jk}(corner_{ijk}) + \beta_{12jk}(victim_{ij}) + e_{ijk} \quad (1)$$

with each of the predictors being grand-mean centered. After initially assuming all coefficients in the above model to be variable across Seattle neighborhoods and census tracts, a simplified model was estimated in which all coefficients that *did not* vary were specified as fixed. The resulting level 2, or between-neighborhood model for the initial random-coefficient regression model for burglary-specific fear of crime is, then, the following:

$$\begin{aligned} B_{0jk} &= \theta_{00k} + u_{0jk} \\ B_{12jk} &= \theta_{120k} + u_{12jk} \\ B_{qjk} &= \theta_{q0k}\ for\ q = 1-11 \end{aligned} \quad (2)$$

and the resulting level 3, or between-tract model is as follows:

$$\theta_{q0k} = \pi_{q00}\ for\ q = 0-12 \quad (3)$$

No coefficients exhibit significant variability across census tracts, as indicated by the between-tract model specified in equation 3, and as the results from the random-effects panel of Table 2 indicate. At the neighborhood level, by comparison, adjusted mean burglary-specific fear varies across neighborhoods, and the effect of burglary victimization on this fear also varies across Seattle neighborhoods.

The fixed-effects panel of Table 2 indicates that nearly all the individual-level predictors included in the model have significant effects on burglary-specific fear. Two of the sociodemographic indicators — age and race — have effects that reach standard levels of significance, although the relationships are opposite in direction to what has been found previously in the fear-of-crime literature. For instance, age is negatively related to fear. The more easily interpreted exponentiated coefficient for age suggests that for each unit increase in age, the odds of experiencing burglary-specific fear decreases by nearly 3%. Further, nonwhites are shown to be less fearful of burglary — nonwhites exhibit approximately 5% reduction in the odds of experiencing fear in comparison to whites. The other sociodemographic variable — gender — is insignificant. These findings seem to completely contradict long-held notions that the elderly, women, and nonwhites are more fearful of crime. Implications of these findings are further discussed below.

Most of the routine activity variables show relationships with burglary-specific fear which indicate that those survey respondents with "more dangerous" lifestyles are more fearful. For example, exposure is positively related to fear: for each unit increase in the access routes and corner residence variables, the odds of experiencing fear increase 4% and 6% respectively. Further, target attractiveness is positively related to fear — the more expensive household goods a respondent owns, the more fearful he/she is of burglary (increasing the odds of fear by nearly 3% for each unit increase in expensive goods). However, the other indicator of target attractiveness — family income — is insignificant in this model. Guardianship seems to have mixed effects on fear. On the one

hand, the more guardianship barriers a respondent's home has, limiting the potential for effective guardianship, the more fearful he/she is of burglary. On the other hand, safety precautions (increasing guardianship) are positively related to fear. So, increased precautionary measures *and* apparent barriers to effective guardianship lead to *elevated* levels of fear even though safety precautions are negatively related to the risk of actual burglary victimization and guardianship barriers are positively related to such a risk (Rountree 1994).

Finally, *previous* experience with burglary victimization increases fear of household break-ins — the odds increase by about 16% compared to those not experiencing such victimization. According to the significant chi-square statistic, this model with individual-level predictors is a significant improvement over a baseline burglary-specific fear of crime model containing only an intercept (varying across neighborhoods and census tracts) and an individual-level extra binomial error term.[6]

TRACT-LEVEL CONTEXTUAL EFFECTS

We estimated next a contextual model in which neighborhood- and tract-level indicators of crime and disorganization are added to the model in an attempt to account for the variability in adjusted mean burglary-specific fear across neighborhoods and the variability in the effect of burglary victimization on fear across different neighborhoods. The level 2, or between-neighborhood model is thus extended as follows in order to incorporate the contextual characteristics of interest while the between-tract model remains unchanged (since there was no variability at this third level):

Level 2 (between-neighborhood) model (4)

$$B_{0jk} = \theta_{00k} + \theta_{01k} busy\,pl_{jk} + \theta_{02k} incivil_{jk} + \theta_{03k} ethnic_{jk} + \theta_{04k}\, integ_{jk} + u_{0jk}$$
$$B_{12jk} = \theta_{120k} + \theta_{121k} busy\,pl_{jk} + \theta_{122k} incivil_{jk} + \theta_{123k} ethnic_{jk} + \theta_{124k}\, integ_{jk} + u_{12jk}$$
$$B_{qjk} = \theta_{q0k}\, for\ q = 1-11$$

Level 3 (between-tract) model (5)

$$\theta_{q0k} = \pi_{q00}\, for\ q = 0-12$$

At level 2, the variability in burglary-specific fear and the variability in the effect of prior burglary victimization on this fear, then, are estimated as functions of grand means, neighborhood-level busy places, incivilities, ethnic heterogeneity, and social integration. At level 3, all effects are specified as fixed. A single-equation model combining the above revised contextual models with the individual-level model (see equation 1) was estimated. Individual and contextual-level variables that were insignificant were dropped from the model one at a time through the process of backwards elimination, and the results from a reduced contextual model for burglary-specific fear are reported in Table 3.[7]

First, the chi-squared statistic presented in Table 3 indicates that this contextual model is a significant improvement over the previously discussed

model containing only individual-level predictors. The random-effects portion of this table reveals a still-significant variance component for adjusted mean burglary-specific fear at level 2, implying that this fear is still significantly variable across neighborhoods. Apparently, the contextual characteristics that were added could not adequately account for the variability in concern about burglary across neighborhoods. Further, the still-significant variance component for the burglary victimization variable indicates that the added contextual variables were not completely adequate in explaining the variability in the effect of burglary victimization on burglary-specific fear across neighborhoods.

The fixed-effects panel of Table 3 reveals some significant contextual main and moderating effects. Specifically, neighborhood-level incivilities exhibit a significant positive effect on burglary-specific fear. Thus, the positive effect of disorder on our measure of fear is consistent with much previous research despite the fact that most of the extant work uses a non-crime-specific, cognitive, assessment-of-risk measure for fear. In contrast, our finding regarding the main positive effect of neighborhood social integration differs from previous studies using such a measure (e.g., Ferraro 1995; Skogan & Maxfield 1981; Lewis & Salem 1986; Taylor et al. 1984).

Beyond the main effects of context, neighborhood incivilities are also involved in a significant negative interaction with burglary victimization. This interaction indicates that the positive effect of previous burglary victimization on burglary-specific fear is most apparent in relatively orderly neighborhoods (those with fewer incivilities). Highly disordered neighborhoods, on the other hand, temper the effect of burglary victimization, indicating that social context — particularly as it relates to levels of incivility — may have a tendency to "overwhelm" individual-level variables in the explanation of fear.

With respect to the individual-level predictors, the fixed-effects panel of Table 3 shows no new findings; the individual-level relationships are very similar to those found in the initial random-coefficient model for burglary-specific fear (see discussion of Table 2).

Results for Perception of Risk

INDIVIDUAL-LEVEL ANALYSES

The individual-level model for the hierarchical analysis of perception of crime risk is identical to that of the burglary-specific fear of crime (see equation 1), except that p_{ijk} is the probability of perceiving one's neighborhood to be either somewhat or very unsafe from crime. As in the previous random-coefficient regression model, all the coefficients from the individual-level model were initially assumed to vary across Seattle neighborhoods and census tracts, and the coefficients for which this assumption was incorrect were subsequently specified as "fixed." Findings from the resulting initial random-coefficient logistic regression model are summarized in Table 4.[8] The chi-squared statistic for this model suggests that this model is a significant improvement over a baseline risk-perception model.

Significant variance components are reported in the random-effects panel of Table 4 at level 3 for adjusted mean risk perception and at level 2 for adjusted

mean risk perception, race, leaving the home unoccupied, and previous burglary victimization. Thus, adjusted mean perception of risk is significantly different across Seattle neighborhoods and census tracts. Furthermore, race, leaving the home unoccupied, and previous burglary victimization have variable effects on risk perception across level 2 units (neighborhoods).

The fixed-effects panel of Table 4 reveals individual-level effects that differ somewhat from those found for burglary-specific fear. Specifically, males are significantly less likely than females to feel danger or unsafe in their neighborhood, but gender was insignificant in the burglary-specific fear model. More consistent with the burglary-specific fear results, findings on race suggest that nonwhites perceive lower risk than their white counterparts and worry less about household break-ins. Age is also negatively related to risk perception, as it was with fear, although the effect appears to be somewhat stronger for burglary-specific fear. In addition to sociodemographic attributes, several other individual-level explanatory variables exert significant main effects on perception of crime and victimization risk. In particular, safety precautions, access routes, and previous burglary victimization are all positively related to risk perception. Thus, the presence of prior victimization experiences and increases in the number of safety precautions and access routes have the effect of heightening perceived risk. Finally, family income is negatively related to perceived risk.

TRACT-LEVEL CONTEXTUAL EFFECTS

The findings for the contextual model for perceived risk are presented in Table 5. The contextual model stems from combining the level 1 model for perceptions of risk with a revised level 2 (between-neighborhood) model that attempts to account for the variability in mean perceived risk and the coefficients for race, home unoccupied, and prior burglary victimization with the addition of neighborhood-level busy places, incivilities, ethnic heterogeneity, and social integration, and a revised level 3 (between-tract) model that attempts to explain the variation in mean perceived risk across tracts with the addition of residential burglary rates. Thus, the revised level 2 and level 3 models are as follows:[9]

Level 2 (between-neighborhood) model (6)

$$B_{0jk} = \theta_{01k} busy\,pl_{jk} + \theta_{02k} incivil + \theta_{03k} ethnic_{jk} + \theta_{04k} integ_{jk} + \theta_{05k} incivil * ethnic_{jk} + u_{0jk}$$
$$B_{3jk} = \theta_{30k} + \theta_{31k} busy\,pl_{jk} + \theta_{32k} incivil_{jk} + \theta_{33k} ethnic_{jk} + \theta_{34k}\, integr_{jk} + u_{3jk}$$
$$B_{4jk} = \theta_{40k} + \theta_{41k} busy\,pl_{jk} + \theta_{42k} incivil_{jk} + \theta_{43k} ethnic_{jk} + \theta_{44k}\, integ_{jk} + u_{4jk}$$

$$\beta_{qjk} = \theta_{q0k}\ for\ q = 1,2,5-11$$

Level 3 (between-tract) model (7)

$$\theta_{00k} = \pi_{000} + \pi_{001} burglary\ rate_k + r_{00k}$$
$$\theta_{q0k} = \pi_{q00}\ \ for\ q = 1-12$$

The purpose of the contextual model resulting from the combining of the level 2 and level 3 models above with the individual-level model for perceived risk is to try to expose the direct and moderating effects of community crime and disorganization on perceived risk. Specifically, we are interested in whether or not the neighborhood-level contextual variables can account for the variability across neighborhoods in adjusted mean risk perception and the relationships between perceived risk and race, home unoccupied, and previous burglary victimization. Likewise, we are interested in whether or not the tract-level burglary rate can account for the variation in adjusted mean risk across Seattle census tracts. The significant chi-squared statistic for this contextual model suggests that it produces an improved fit as compared to the random-coefficient model containing only the individual-level characteristics.

The random-effects panel of Table 5 shows that the contextual model is somewhat successful in that adjusted mean perceived risk is no longer significantly variable across Seattle census tracts. On the other hand, adjusted mean risk perception remains significantly variable across neighborhoods, and the effects of race and burglary victimization on this risk perception are still variable across neighborhood units. The effect of leaving the home unoccupied on this risk, however, is no longer variable across neighborhoods. Thus, the addition of the contextual indicators of crime and disorganization was most effective in accounting for the between-tract differences in adjusted mean perceived risk and between-neighborhood differences in the effects of leaving the home unoccupied on this risk, although it should be noted that most of the variance components in Table 5 represent substantial declines in comparison to those reported in Table 4.

The main and interactive effects for the contextual variables are described in the fixed-effects panel of Table 5. For instance, neighborhood incivility has a positive effect on perceived risk. The significant interaction between incivilities and heterogeneity suggests that the positive effect of incivilities on perceived risk is stronger in ethnically heterogeneous areas. Neighborhood-level community integration is negatively related to perceived risk, and the tract-level residential burglary rate has a positive and significant effect on perceived risk.

Contextual characteristics also exhibit some moderating effects. In such cases, indicators of crime or disorder *condition* the effects of the individual-level attributes. For instance, neighborhood incivilities "contextualize" the effects of race on perceived risk. The significant negative interaction between race and neighborhood incivilities suggests that the finding that nonwhites feel less risk than whites is especially strong in relatively disordered neighborhoods. In very orderly neighborhoods, on the other hand, the negative effect of being nonwhite on risk perception is much weaker. Neighborhood incivilities also condition the effect of leaving the home unoccupied. Exposure by leaving one's home unoccupied at night leads to greater fear, particularly in relatively disorderly neighborhoods. The effect of leaving the home unoccupied is tempered somewhat by relative order and civility within the social context.

The individual-level effects on perceived risk in the contextual model are similar to those found in the estimation of the initial random-coefficient regression model for risk perception (see discussion above). In short, men, nonwhites, and older respondents feel less danger (although age is only

significant at the .10 level in the contextual model), while safety precautions, access routes, and burglary victimization increase perceived risk. The main effect of family income — significant in the random coefficient regression model for perceived risk — is insignificant in the contextual model.

Discussion and Conclusion

The findings from the foregoing analyses suggest that, indeed, there are some important distinctions between a cognitive assessment of risk within one's neighborhood — a measure regularly referred to as "fear" in the fear-of-crime literature — and an emotionally based, crime-specific fear — in particular, burglary-specific fear. These distinctions occur in individual-level effects and contextual effects. Further, micro-macro interactions are distinct for each of the respective concepts.

As alluded to previously, some of the results discussed here contradict earlier work on fear of crime, perhaps because of differences in the concept of *fear*. For instance, our research indicates that younger people and whites are more fearful of burglary, while gender has an insignificant effect on burglary-specific fear. Most of the literature, however, stresses that the elderly, women, and nonwhites fear crime more than other sociodemographic groups. However, most of these previous studies focus on cognitive assessments of neighborhood safety, similar to the risk perception measure used here. Thus, risk perception and actual fear may have different sociodemographic predictors. Partially in support of such a proposition, we find that age is a much more marginally significant predictor of perceived risk, and men are significantly less likely to feel unsafe than women. More consistent with the burglary-specific fear analysis, nonwhites feel safer (less risk) than whites, although in the case of risk perception the effect of being nonwhite interacts with neighborhood incivilities in such a way that nonwhites are particularly less likely than whites to feel unsafe in highly disordered communities. Income — a sociodemographic variable that can also be viewed as a proxy for target attractiveness — appears to be a somewhat better predictor of risk perception in comparison to burglary-specific fear. Though the effect of income on risk perception falls just below the .10 level of significance in the contextual model, it had a significantly negative effect on risk perception in the random coefficient regression model (Table 4). In contrast, income is not a significant predictor of burglary-specific fear, and the direction of the effect is positive. Overall, then, we cannot make the claim that the sociodemographic predictors for fear of crime (household burglary, specifically) and perceived risk are identical.

Beyond sociodemographic findings, other significant microlevel predictors of fear of crime and perceived risk include various routine activities. For the most part, those respondents whose activities left them more vulnerable (i.e., had more expensive goods, more guardianship barriers, access routes, etc.) tended to be more likely to fear crime or feel that their neighborhood was unsafe, although this pattern holds more so for burglary-specific fear than it does for risk perception. Such findings should be stronger for burglary-specific fear, however, given that many of the routine activity measures tap household

vulnerability specifically rather than the vulnerability of a resident in the neighborhood irrespective of residence.

Previous experience with household burglary behaves similarly with respect to both fear and perceived risk — it is a key individual-level predictor of both measures. Previous burglary victimization heightens concern about a repeat burglary (thus increasing burglary-specific fear) as well as increasing the likelihood that one will evaluate one's neighborhood as unsafe. The positive effect of burglary victimization on burglary-specific fear is particularly strong in relatively orderly neighborhoods.

The individual-level predictors discussed above also exhibit differing degrees of variability across contexts in their effects on burglary-specific fear versus perceived risk. Our results showed, for instance, that adjusted mean risk perception varied across tracts and neighborhoods, while adjusted mean burglary-specific fear varied only across neighborhoods. In short, the variation in burglary-specific fear seems to be partitioned quite differently across contextual units than is the variation in perceived risk. The relationships between risk perception and the race and home unoccupied variables were variable across neighborhoods, whereas neither of these variables had differential effects on burglary-specific fear across neighborhoods. Previous burglary victimization, however, did vary in its effects on both fear and perceived risk. Notice that contextual variables interact uniquely with individual-level predictors for burglary-specific fear and risk perception. This interaction is related to the differences in the variability across contexts in individual-level predictors.

We found both similarities and differences among risk perception and burglary-specific fear concerning the main effects of contextual factors. First, neighborhood incivilities are positively related to both burglary-specific fear and risk perception, although this effect appears much stronger for fear than for perceived risk, affirming, to a certain extent, previous work by LaGrange et al. (1992).

An interesting difference between the contextual predictors of burglary-specific fear and perceived risk occurs in relation to the social integration measure. Our findings show that neighborhood cohesion is significantly and negatively related to perceived risk, indicating that social integration serves to diminish residents' perceptions of the neighborhood being unsafe. The relationship between integration and burglary-specific fear, however, is significant and positive. In brief, social integration is found to influence positively fear about household burglary, yet it is negatively related to perceived risk. It is plausible that residents of a relatively close-knit community would feel better about the safety of their neighborhood as a whole — they are probably more likely to feel as if there is adequate informal social control and social support, and this perception is perhaps reflected in a more positive evaluation of the neighborhood's safety. However, community cohesiveness is positively associated with neighborhood socioeconomic status (SES).[11] Perhaps due to the often-found positive relationship between high income and burglary victimization risk, then, residents of integrated communities are more fearful of burglary specifically, though they perceive their neighborhood, overall, to be relatively safe from crime or disorder in general — if these people are going to become victimized,

it is more likely to be of the property-victimization variety. On the other hand, residents of less integrated areas that have more "pressing" victimization concerns; burglary is perhaps the least of their worries.

The literature suggests that residents of integrated communities are more informed about neighborhood events and issues because news and information are well disseminated among cohesive neighbors (Liska & Baccaglini 1990). If the news shared includes information on crime in the neighborhood — occurrences that are more likely to be nonviolent in integrated, prosperous areas — burglary-specific fear levels may rise precisely *because* the community is well integrated. Thus, integration may be positively related to burglary-specific fear because those communities likely to fear burglary — higher-income areas — are most well equipped structurally to disseminate information on break-ins, thereby increasing residents' concerns.

On the other hand, lack of social integration creates an increased sense of danger among residents in the community. Poor integration, along with other indicators of disorganization often plaguing communities in which people feel unsafe (i.e., high crime rates, many incivilities, etc.), serves to increase perceptions of danger by delineating the disorganized state of the neighborhood. In poorly integrated neighborhoods, residents are lacking a strong potential source of social support and informal social control and are thus more likely to negatively evaluate their community's overall safety.

Finally, tract-level burglary rates have a positive impact upon perceived risk. The effect of burglary rates on burglary-specific fear was not estimated due to the insignificant variability in adjusted mean burglary-specific fear across census tracts. Despite the fact that residents of prosperous areas are more likely to experience burglary than, say, violent crime, burglary is also high in poor areas. High burglary rates in either type of neighborhood appear to increase the perception of risk. Consequently, high burglary rates in high-SES neighborhoods could perhaps serve to *buffer* the risk-reducing effects of low incivilities and high integration, whereas high burglary rates in low-SES neighborhoods *reinforce* the effects of other indicators of disorganization likely found in such areas.

In sum, though there were some similarities between risk perception and fear of crime, our findings generally provide further empirical support for the notion that fear and perceived risk represent conceptually distinct constructs. Most previous research ignores substantively important distinctions between different reactions to crime, mainly due to the nearly exclusive focus on measures that tap judgments about risk or assessments of the potential for experiencing crime. However, consistent with recent work in the fear-of-crime tradition that has begun to examine risk as only one of several components of fear (e.g., see Warr & Stafford 1983; Warr 1987; LaGrange, Ferraro & Supancic 1992 — all reviewed earlier), we find that the predictors of traditional measures of fear (risk) can be very different from predictors of an emotional response to burglary victimization. Future work investigating issues surrounding fear of crime should, therefore, continue to be sensitive to the measures used, bearing in mind that a very different set of factors may explain perceived risk or feelings of "urban unease" as opposed to actual crime-specific fear.

Notes

1. We did not delete all cases with missing data on income. Instead, we imputed missing values on income using a group-mean substitution method. Those observations with responses missing for income were assigned a value equal to the mean score for their particular city-block pair.

2. Both the risk perception and fear of crime measures have four-item ordinal response scales associated with their respective items in the Seattle survey. Although multilevel modeling procedures recently have been extended to ordinal logistic regression, in this paper we wanted to present multilevel models most familiar to users and readers. Thus, we decided to dichotomize the response categories, so that the resulting binary response variable could then be estimated with a standard hierarchical logistic model. Ordinal logit models (nonhierarchical) were estimated in order to discern the most appropriate way in which to split the response categories into a dichotomy (Winship & Mare 1984). Results indicated that burglary-specific fear was best dichotomized into groups of worrying about a break-in once a week or daily compared to worrying about being burgled once a month or less. Further, the results indicated that the measure for risk perception was best split into categories of perceiving the neighborhood to be either somewhat or very unsafe as opposed to somewhat or very safe.

3. See Brantingham and Brantingham (1981) or Felson (1994) for a more thorough discussion of the relationship between crime and exposure as related to the ecology of crime.

4. An anonymous reviewer of an earlier draft of this article expressed concern over the possible redundancy of our measures for target attractiveness. The correlation between family income and expensive goods is .409. We estimated models for both fear and perceived risk with (1) both expensive goods and family income in the models, (2) with expensive goods but without family income, and (3) with family income but without expensive goods. The coefficients were very similar across all models, and the significance of none of the variables changed. Since it appeared as if results were not being affected by multicollinearity, we have chosen to include both target attractiveness measures in the models presented here.

5. Since some scholars are critical of using aggregated individual-level data as contextual data, we have compared logistic regression models with aggregated individual-level data (at the tract level) to models with comparable census measures (also at the tract level) and have found that we get very similar results. The only discrepancies occur between models with different contextual variables tapping population age structure and population mobility (e.g., the aggregated measure for tract-level percent aged 17-29 was significant while the census measure for percent aged 17-29, in another model, was insignificant and the aggregated measure for residential mobility was significant while the census measure, in another model, was not). These two discrepancies make more sense if one considers the fact that the sample under-represents young adults and movers. Given the overall consistency in our comparisons, however, and the fact that the sample was not biased in a way which could conceivably affect our aggregated individual-level data (we don't use mobility or age-structure contextual measures), we feel confident that the aggregated survey measures serve as reasonable proxies for truly contextual data.

6. The purpose of this individual-level extra binomial error term is to allow for the possibility that the variances of the individual-level sample fear response probabilities are not distributed precisely as a binomial variable on the basis of the expected values of the estimated logistic regression model. In general, if the variance component corresponding to this term is estimated to be greater (lesser) than 1.0, then the variance in the fear responses at the respondent level is greater (lesser) than would be expected if the conditional probability of the fear responses followed the pure binomial distribution of the standard logistic regression model. The estimates in Table 2 indicate that this error-term variance is statistically significant and thus that there is evidence for extra-binomial variance at the individual level.

7. We recognize that it is standard in hierarchical modeling procedures to attempt to separate the distinct effects of individual-level sociodemographic variables from compositional effects by including compositional measures (e.g., percent male, percent nonwhite, mean age, mean income) in the contextual model. In models not shown here, we have followed such a strategy. However, significant problems with multicollinearity arise when including such compositional

measures at both the neighborhood and tract levels as well as disorganization-related contextual variables. Further, we found the incorporation of the compositional variables to have little effect on the other effect coefficients and thus chose to present the simpler contextual model, without compositional measures, in this paper. However, since we know that the coefficients are virtually unaffected by the inclusion of compositional measures, we feel confident that individual-level effects discussed in our models represent real individual-level effects rather than unmeasured compositional differences between neighborhoods or census tracts.

8. As in the case of the burglary-specific fear models, all variables in the analyses of perception of risk are grand-mean centered.

9. We also considered the possibility that there may be interactions between several of our contextual characteristics. While such interactions were generally insignificant, note that we did include an interaction term for incivilities * heterogeneity in order to explain variability in the intercept (adjusted mean perceived risk, in this case).

10. Remaining inconsistencies between our sociodemographic findings and previous "fear" research (after taking into account differences in measures) could be partially attributed to the fact that our findings are net of the effects of victimization risk factors, such as exposure, target attractiveness, etc. Many of the early studies did not account for such factors. See Stafford and Galle (1984) for a discussion of potential pitfalls in failing to account for exposure to risk.

11. Neighborhood-level social integration and neighborhood-level income have a zero-order correlation of .583.

Self-Determination as a Source of Self-Esteem in Adolescence*

TIMOTHY J. OWENS, *Indiana University at Indianapolis*
JEYLAN T. MORTIMER, *University of Minnesota*
MICHAEL D. FINCH, *University of Minnesota*

Abstract

This research examines the effects of the sense of self-determination in three spheres of male adolescents' lives (the family, the school, and the workplace) on positive self-esteem, using five waves of panel data from the Youth in Transition study (grade 10 to five years after high school). Though the self-concept literature has emphasized social sources of self-evaluation, these analyses point to the importance of generalization and attribution processes. It is concluded that the same kinds of experiences that have been found to foster positive psychological outcomes in adulthood — personal discretion in decision making and interesting, challenging tasks — have developmental significance in adolescence as well.

The development of the self-concept has long fascinated social scientists, since Cooley (1902) formulated the "looking glass self" and James (1892) and Mead (1934) distinguished the "I" and the "me." In some respects, the individual's self-image is a direct consequence of interpersonal processes, as suggested by Rosenberg's (1981) principles of "reflected appraisals" and "social comparisons." While social sources of the self-image have received predominant emphasis in the self-concept literature (Gecas & Schwalbe 1983; Wylie 1979), these are not the only bases of self-image formation.

Rosenberg's principle of self-attribution (1981) posits that persons form conclusions about themselves by observing their own performances and attainments. Though the standards for such self-evaluations derive from social values and expectations, the direct mediation by others in producing these

** This research was supported by grants from the National Institute on Aging (AG03325), the University of Minnesota Computer Center, and the IUPUI Office of Integrated Technology. The authors would like to thank Geoffrey Maruyama for his comments and advice throughout the data analysis, Melvin Kohn for several very helpful suggestions on an earlier draft, and the participants in the Indiana University Program Seminar on Identity, Self, Role, and Mental Health. Portions of this article were presented at the annual meetings of the American Sociological Association, Washington, D.C., August 1995.* *Direct correspondence to Timothy J. judgments is unnecessary. The meaning assigned to one's observations of self is of foremost importance (Rosenberg 1981; see also Markus, Cross & Wurf 1990; Owens 1993). Achievements will be seen as reflecting the self when they are internally caused or motivated, not the result of external forces. Rosenberg and Pearlin (1978) use the principle of self-attribution to explain the absence of a relationship between social class and self-esteem among children. For children, socioeconomic status is ascribed, reflecting the parent's accomplishments. According to the investigators, the child's own achievement influences the developing self. Consistently, psychological research, grounded in self-perception (Bem 1972) and self-attribution (Kelley & Michela 1980) theories, has shown that when people conceive their behavior as internally motivated, as determined by their own volition, there are stronger consequences for the self (Condry 1977; Deci 1975; Weiner 1979).[1]

Much research on adult self-concept development emphasizes the importance of achievements and attainments (Andrisani & Nestel 1976; Cohn 1978; Elder 1969, 1974; Goodwin 1977; Gurin & Gurin 1976; Jacques & Chason 1977; Luck & Heiss 1972; Owens 1992a). Kohn and Schooler (1973, 1983; Kohn 1969) have elucidated the causal processes involved by identifying the components of social class position that influence psychological functioning. Their analyses show that experiences of self-direction at work are of crucial importance (Kohn & Schooler 1983; Slomczynski, Miller & Kohn 1981). Other investigators have similarly emphasized autonomy as a source of self-esteem and a sense of competence (Franks & Marolla 1976; Gecas & Schwalbe 1983; Korman 1970; Mortimer, Finch & Kumka 1982; Mortimer & Lorence 1979b; Spenner & Otto 1985). Research on the effects of self-direction have been extended to housework (Schooler et al. 1984; see also Olsen 1974) and to the schoolwork of children (Miller, Kohn & Schooler 1982).[2]

According to Kohn and Schooler (1983), the effects of work conditions on the personality can be explained by a generalization process: "a direct translation of the lessons of the job to outside-the-job realities" (290). Kohn's generalization model is similar to Rosenberg's principle of self-attribution, though the latter is formulated more specifically with reference to the self-concept. For both, psychological development occurs through the resolution of important problems (Kohn 1976; Kohn & Schooler 1973; Rosenberg 1981). If individuals experience self-direction, successfully adapt to the challenges facing them, and attribute their successes to themselves, they will come to view themselves as capable and worthy.

In the present study, we extend these investigations to the period of adolescence, using five waves of panel data from Bachman's (Bachman, O'Malley & Johnston 1978) Youth in Transition study. We examine the implications of a sense of self-determination and control for the development of self-esteem in three central spheres of adolescents' lives: the family, the school, and for those who hold part-time jobs while still in school, the workplace. Further, it is worth noting that while many authors have discussed the importance of adolescence in developing a basic sense of competence, efficacy, and worth (e.g., Clausen 1991, 1993; Markus, Cross & Wurf 1990; Owens 1994), linkages between the macro aspects of institutional context and self-esteem have been neglected (see Owens 1992a for an attempt to link social context to self-

esteem). In the present study we aim to bridge this gap by explicitly examining whether the perception of freedom and autonomy in three key adolescent spheres of development — the family, the school, and the workplace — are generalized and ultimately attributed to the self, thereby contributing to a sense of self-esteem or worth. In so doing, we take an underlying ecological perspective (Bronfenbrenner 1979). That is, we seek to understand whether subjective experiences of control and freedom in three macro spheres influence the developing individual.

Our theoretical rationale for linking self-attribution and generalization processes is aided by self-determination theory (Deci, Eghrari & Patrick 1994; Deci & Ryan 1985). According to this view, the nature of involvement in, and perception of, a social context influences the internalization and integration of values and regulatory processes associated with that context. As the "person identifies with the value of an activity and accepts full responsibility for doing it . . . one's behavior emanates from one's self; it is self-determined" (Deci, Eghrari & Patrick 1994:121). Expanding this process to the present study, the greater the *perception* of self-determination in the three contexts under examination, the more positive the impact on a youth's sense of self-esteem and worth.

Turning first to the family context, research on the effects of parental control on adolescent development is quite consistent with the principles of attribution and generalization. It appears that the optimal control strategy, fostering a wide range of positive child outcomes (including self-esteem), is participative (Bowerman & Elder 1964; Elder 1962, 1963, 1968; Kandel & Lesser 1972; Lamborn et al. 1991; Rollins & Thomas 1979). The parent shares decision making with the adolescent. The use of reasoning, the information provided by parents, and the child's active participation in decision making foster a sense of efficacy in coping with problems (Barber & Rollins 1990; Rollins & Thomas 1979; Steinberg, Mounts & Lamborn 1991). Moreover, external coercive control generally has negative consequences (Clausen 1993; McLeod & Shanahan 1993), while democratic control practices "induce within the child internalized motivation for his behavior" (Rollins & Thomas 1979; see also Dornbusch 1989; Lamborn et al. 1991).

Since much of the adolescent's time is spent in school, the structuring of the educational environment could also have implications for the developing self-image (Covington 1992). Self-directed school experiences, like democratic patterns of parental control, may foster internally motivated behavior.[3] When the school environment provides a context for self-initiated activities, there are stronger and potentially more positive implications for the self than under conditions of external control (Weiner 1979; see also Covington 1992).[4] Intrinsic motivation has also been found to heighten academic achievement (Condry 1977; Weiner 1979), which has similar positive consequences for the self (Brookover, Thomas & Paterson 1964; Calsyn & Kenny 1977; Maruyama, Finch & Mortimer 1985; Purkey 1970; Rogers, Smith & Coleman 1978). We therefore expect that if the student develops an intrinsic motivation toward schoolwork, these experiences will have positive implications for self-esteem.

The workplace is increasingly a third institutional context for personal development in adolescence (Greenberger & Steinberg 1986; Mortimer et al. 1992). In the Youth in Transition panel, 35% of the students were employed in

the tenth grade and 55% by the end of the twelfth. Whereas some commentators have been optimistic about the implications of work activities for adolescent development (Coleman 1974; Finch et al. 1991), others are more pessimistic (Steinberg, Fegley & Dornbusch 1993; Steinberg, Mounts & Lamborn 1991). Analyses of the Youth in Transition data suggest that long hours of work may depress academic achievement (Finch & Mortimer 1985; Mortimer & Finch 1986b), but assessment of a more recent cohort, in the Youth Development study, indicates that work intensity has little developmental effect (Mortimer, Shanahan & Ryu 1993). However, it must be remembered that adolescent employment, like that of adults, differs on several dimensions (Bachman, O'Malley & Johnston 1978; Greenberger, Steinberg & Ruggiero 1982); it is increasingly evident that the full impacts of working depend on the nature of that experience (Finch et al. 1991; Mortimer, Shanahan & Ryu 1993; Mortimer & Shanahan 1994; Shanahan et al. 1991). Extending this work, we investigate the effects of intrinsic motivation in work on the development of self-esteem.

In summary, this study assesses the implications of the sense of self-determination in three spheres — the family, the school, and the workplace — for the developing adolescent self-image. In doing so, we extend Rosenberg's self-attribution and Kohn's generalization theories to adolescent development.

Data Source

The data are from Bachman's (1974) Youth in Transition study, a five-wave longitudinal study with a multistage sampling design representing 2,213 tenth-grade boys attending 87 public high schools in the continental U.S. in the fall of 1966. We use data from all five waves: wave 1 (tenth grade, approximately 15 years old), wave 2 (eleventh grade, 17 years old), wave 3, (twelfth grade, 18 years old), wave 4 (one year after high school, 19 years old), and wave 5 (five years after high school, 23 years old). Wave 1 data were collected in the fall in the subjects' schools; subsequent waves were collected in the spring at such "neutral sites" as libraries, community centers, and churches, except for the final wave, which was by mailed questionnaire. (The original sample was weighted to correct for school size. All analyses reported here are based on the weighted panel, N = 2,154 in grade ten.)

Although attrition is a major problem in panel studies, 73.5% of the original study participants were included in the final wave (Bachman, O'Malley & Johnston 1978). There were greater losses among African Americans, dropouts, persons of lower socioeconomic background, and persons of lower intelligence.[5] To assess the severity of these losses, Bachman and his colleagues performed an analysis of the relations among the wave 1 variables for the wave 1 and wave 5 respondents. Judging from the similarity of the correlations, they concluded that biases resulting from sample attrition are not serious, particularly if the intent is to estimate relations among variables, not the absolute size of population parameters. Moreover, analyses of data from a control group, queried only at times 1 and 4, indicate no systematic biases from repeated measurements.

Given the relatively small number of African Americans (N = 98), especially in the fifth wave, our analyses are confined to the white panel members. Further

justifying their exclusion, Bachman, O'Malley, and Johnston (1978) caution that because the African American students were highly concentrated in a small number of schools, what appear to be racial differences may actually be school effects. Furthermore, our analyses exclude persons with missing data on any of the variables in each model. We study the remaining pool of subjects through all five waves of data collection. (For the family model 965 respondents provided the data and 967 for the school model.)[6] In estimating the work model, we restrict the analysis to students who were working during the eleventh and twelfth grades ($N = 222$). This restriction focuses attention on those who manifest a rather strong attachment to the labor force.

Bachman, O'Malley & Johnston (1978) find that adolescent self-esteem is positively related to the quality of family relations, positive school attitudes, and ambitious job attitudes, thus showing that attitudes about these important life domains and the self are intertwined. However, Bachman has not focused directly on self-determination in these spheres of life as sources of self-esteem.

Conceptualization and Measurement of the Constructs

AUTONOMY IN FAMILY, SCHOOL, AND WORKPLACE

Research on social structure and personality has pointed to autonomy, or specifically to occupational self-direction, as a central determinant of adult psychological change (House 1980). Kohn and Schooler's (1982:1259) approach emphasizes the job's objective structure as providing opportunities for "the use of initiative, thought, and independent judgment." Mortimer and her colleagues (Mortimer & Finch 1986a; Mortimer & Lorence 1979a, 1979b; Mortimer, Lorence & Kumka 1986) have used the term *work autonomy* to refer to other experiences of work that are implied by "occupational self-direction," including the subjective appraisal of challenge, with findings that closely parallel Kohn and Schooler's work. But the level of congruence between objective and subjective job assessments has been the subject of some controversy (House 1981; O'Brien 1986). Some argue that the objective conditions of work (optimally measured by a job analyst) are what really matter for psychological change (Kohn 1980, 1981). Others take the position that the person's subjective perception is of primary importance (e.g., Griffin 1983; Pfeffer 1981). Research on job satisfaction (Mirowsky 1987; O'Brien 1986; Seashore & Taber 1975) and health (House 1981) suggests that the perception of one's job attributes is a more potent influence on the response to work than the objective situation. But this may not be the case for other psychological phenomena, such as self-esteem.

We view the person's sense of self-determination as one subjective outcome of what Kohn and Schooler (1983) call self-direction. If the structure of activities in the family, school, or workplace allows independent judgment, one would likely perceive one's acts as self-determined and controlled. Complexly structured activities would generally be more interesting and challenging, stimulating an intrinsic motivation to engage in them. Thus, a sense of self-determination may arise from the amount of autonomy permitted by the environment or by the attractive and engaging features of the activity itself. It is conceivable that even in a highly structured and authoritarian classroom

situation, a student may find the subject matter of such inherent interest that schoolwork is viewed as internally motivated, stemming from one's own desire to learn. Though we believe that substantively complex and autonomous environments foster a sense of self-determination and intrinsic motivation, we hypothesize that the subjective phenomenon itself will have positive consequences for self-esteem, irrespective of its sources.

Surely, the ideal study would have measures both of the objective environment and of subjective perceptions to allow assessment of the relationships between them and their effects on self-esteem. The objective structuring of the situation may influence self-esteem and other psychological variables mainly indirectly, through the subjective phenomena of self-determination and control. Still, a number of researchers contend that in order to understand how social contexts influence development and change, it is imperative to gauge the individual's subjective assessments and perceptions of his or her social environment and relationships with others (see Mortimer & Lorence 1995).

In the present study, only self-report data are available, thus precluding truly objective measurement. Furthermore, the questions asked pertain more to the respondent's feelings of intrinsic motivation and control than to the amount of autonomy inherent in the structure of activities or to the character of the environment. This is especially true of the school and work contexts. The family measures focus on decision-making processes and thus more closely reference the environmental structure. All measures appropriately address the sense of self-determination in important spheres of adolescents' lives.

We performed a confirmatory factor analysis using LISREL 7 (Jöreskog & Sorböm 1989) to estimate parameters and to test the overall goodness of fit of the three context-specific self-determination measurement models (as well as the self-esteem measurement model). Assessment of fit helps determine whether a given theoretical model adequately describes the pattern of relationships within a set of data.[7]

Self-Determination in the Family

Four questions related to participation in decision making were used to measure the sense of self-determination in the family. All questions were measured on a 5-point scale (the first and last response options are listed in parentheses below each item).

(1) How much influence do you feel you have in family decisions that affect you? (A great deal . . . Little or no influence)
(2) How often do your parents listen to your side of the argument? (Always . . . Never)
(3) How often do your parents talk over important decisions with you? (Always . . . Never)
(4) How often do your parents act fair and reasonable in what they ask of you? (Always . . . Never)

Bachman (1970:20) labeled these items "amount of reasoning with son." If adolescents feel they influence decisions that affect them, if parents listen, talk over decisions, and are "reasonable," we might conclude that the adolescents have some control in the family domain. As Figure 1 indicates, the model fits

the data well, with a fit ratio of 3.47 ($\chi^2 = 52.02$, df = 15) and a goodness-of-fit index (GFI) of .993.

Self-Determination in School

While the items for the family domain focus on patterns of decision making, the measures in the school sphere express the perception that one's activities in school are internally directed and controlled. If schoolwork is seen as internally motivated, determined by one's own volition because of its "special meaning" and "interest," or because it gives "a chance to learn" or to improve one's "ability to think and solve problems," it will have positive implications for the self (Condry 1977; Covington 1992; Deci 1975; Rosenberg 1981; Weiner 1979).[8] Again, all items were measured on a 5-point scale, with the first and last response options listed in parentheses.

(1) I put a great deal of myself in some things at school because they have special meaning or interest for me. (Very much . . . Not at all)
(2) I enjoy school because it gives me a chance to learn many interesting things. (Very much . . . Not at all)
(3) I like school because I am improving my ability to think and solve problems. (Very much . . . Not at all)
(4) How interesting are most of your courses to you? (Very exciting and stimulating . . Very dull)

The measurement model for school self-determination (Figure 2) also fits the data reasonably well, with a fit ratio of 4.72 ($\chi^2 = 202.82$, df = 43) and a GFI of .977.

Self-Determination in the Workplace

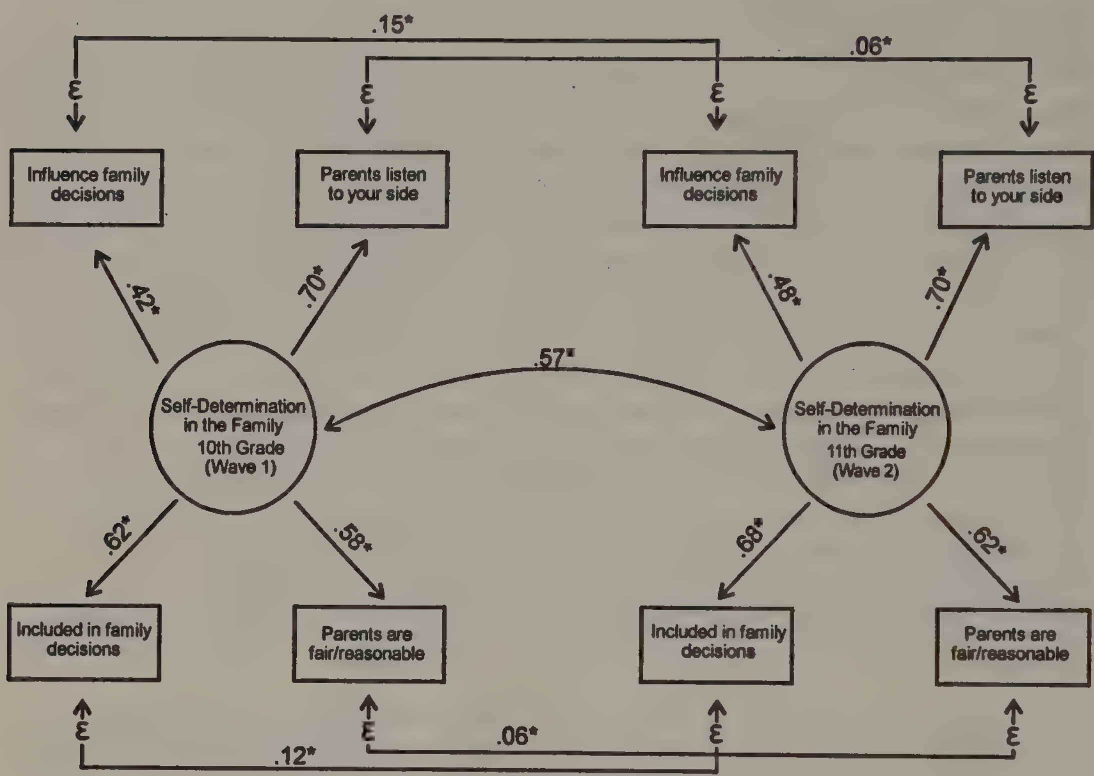
In the work sphere, the first item taps the nature of supervision. The others pertain to one's subjective orientation to the work itself. All items were again measured on a 5-point scale, with the first and last response options listed in parentheses.

(1) How often do you get a chance to work with a supervisor in planning what your work will be — like what you will be doing, or how you should do it? (Almost always . . . Never)
(2) How often are you interested enough to do more work than your job requires? (Most of the time . . . Never)
(3) How often do you feel the work you are assigned on your job is meaningful and important? (Almost always . . . Never)

The more the job is perceived as "interesting," "meaningful," and "important," the more it will provide the basis for a sense of intrinsic motivation and control. These three measures were positively related to a fourth, "How much does your job give you a chance to be independent?" Because this item was missing in the third wave of data collection, however, it was not included in the construct. The measurement model for work self-determination (Figure 3) fits the data well, with a fit ratio of 1.34 ($\chi^2 = 6.71$, df = 5) and a GFI of .994.

Despite the character of jobs typically held by teenagers (almost three-quarters of the employed eleventh-graders in the panel worked as operatives,

FIGURE 1: Measurement Model of Self-Determination in the Family



$\frac{\chi^2}{df} = \frac{52.02}{15} = 3.47$ GFI = .993 *$p<.05$

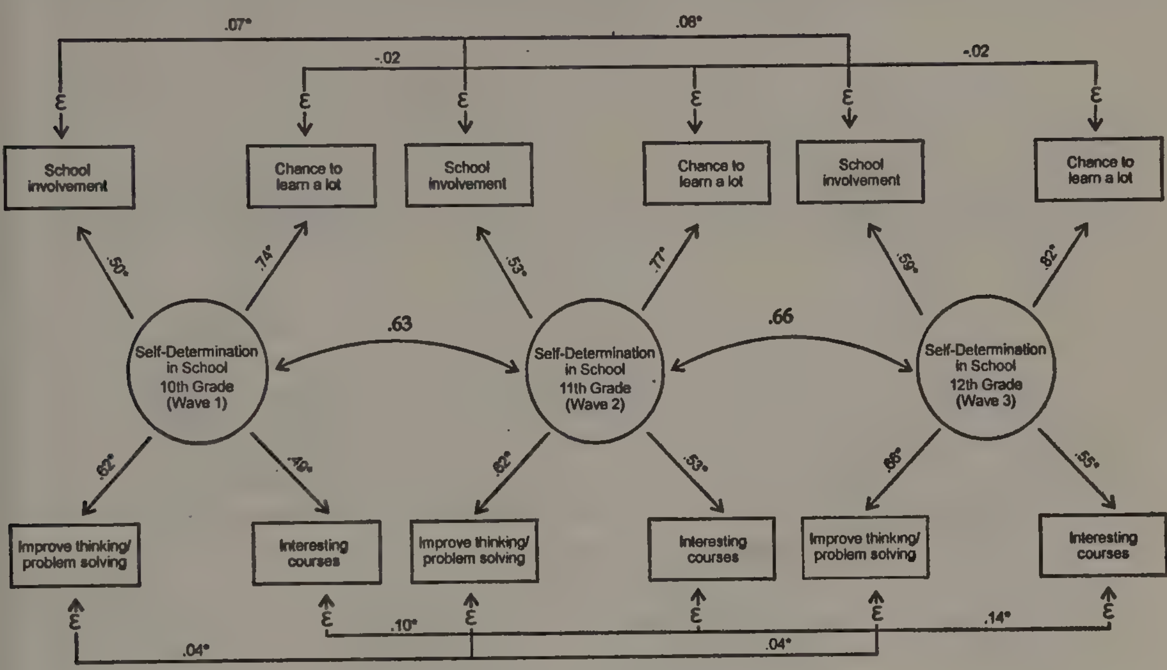
service workers, or laborers), the responses to these items were rather positive. Of the students included in this analysis, 38% said they "almost always" or "often" get a chance to plan their work with a supervisor; 46% were interested enough "most of the time" to do more work than required; and 63% felt "almost always" or "often" that their work was meaningful and important.

SELF-ESTEEM

We use four positively worded items from the Rosenberg Self-Esteem Scale (Rosenberg 1979) to form our self-image construct, which may be considered positive self-esteem or self-worth (Owens 1994). For convenience and brevity, we refer to this construct simply as self-esteem. The responses, on a 5-point scale, ranged from "almost always true" to "never true."

(1) I feel that I'm a person of worth, at least on an equal plane with others.
(2) I feel that I have a number of good qualities.
(3) I am able to do things as well as most other people.
(4) I take a positive attitude toward myself.

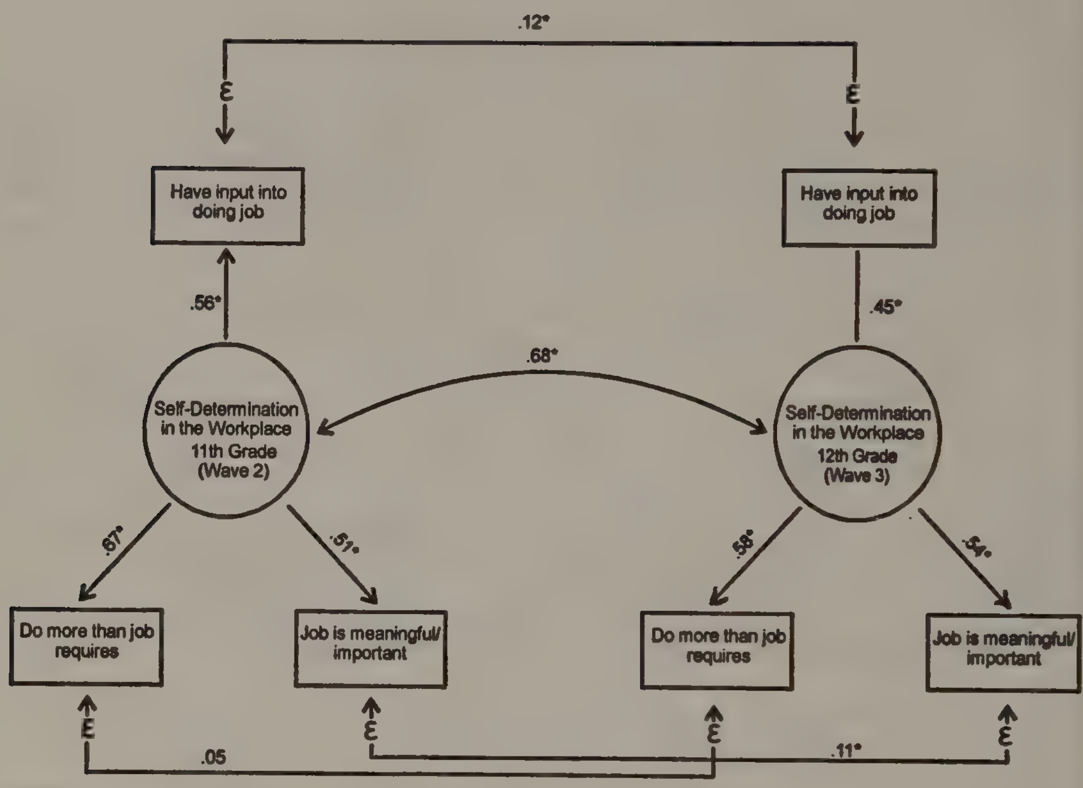
FIGURE 2: Measurement Model of Self-Determination at School



$\frac{\chi^2}{df} = \frac{202.82}{43} = 3.47$ GFI = .977 *p<.05

The theoretical and empirical bidimensionality of the self-esteem construct has been established elsewhere, with the same data set, using confirmatory factor analyses and analyses demonstrating construct validity (Owens 1993, 1994). When a unidimensional self-esteem model (including positive and negative self-esteem items in a single construct) was directly compared to a bidimensional model (consisting of two self-esteem constructs corresponding to self-depreciation and positive self-worth), the data clearly supported the bidimensional construct (Owens 1993). (Self-depreciation consists of negatively worded items such as "I feel I do not have much to proud of" and "Sometimes I think I am no good at all.") A second-order factor analysis of all positive and negative items (which posited self-depreciation and positive self-worth as derived from global self-esteem) corroborated the appropriateness of the bidimensional model (Owens 1993). Furthermore, positive self-worth was more strongly linked than self-depreciation with prosocial and proactive behaviors and attitudes and indicators of self-development; while self-depreciation was more strongly associated with depression, distress, isolation, and dependence. Since the present study's chief aim is to assess the potential *benefits* of a sense of self-determination on well-being — as expressed through one's conception of self — we focus on the positive dimension of self-esteem. (In support of our decision, analyses using a self-depreciation construct yielded little additional insight.)

FIGURE 3: Measurement Model of Self-Determination at the Workplace



$\frac{\chi^2}{df} = \frac{6.71}{5} = 1.34$ GFI = .994 *p<.05

ACHIEVEMENT

The measure of academic achievement is the respondent's self-reported grade-point average. For tenth- and eleventh-graders, queried in the fall and spring, respectively, the question read: "What is the average grade you got in your classes last year?" Twelfth-graders were asked in the spring: "What is the average grade you are getting in your classes this year?" In each case, the responses indicate the level of achievement in school over the past year. (Dornbusch, Ritter & Steinberg 1991 discuss the appropriateness of self-reported grades in comparison to grades obtained from school records; they report a correlation of .79 between these two GPA measures.)

ABILITY

The five measures of intellectual ability (Bachman 1970) are the Quick Test of Intelligence (Ammons & Ammons 1962); the Gates Test of Reading Comprehension (Gates 1958); part J, Vocabulary, and part I, Arithmetic Reasoning, of the

General Aptitude Test Battery (Super 1957); and a newly constructed test, similar to Raven's (1951) Progressive Matrices. (Their respective standardized loadings — which were derived from confirmatory factor analysis — are .70, .77, .86, .60, and .46)

SOCIOECONOMIC BACKGROUND

The socioeconomic background indicators are the father's education (.81), the mother's education (.50), and the father's occupational status — the Duncan socioeconomic index (.76).

Causal Model Specification

We estimated three models (Figures 4, 5, and 6), allowing separate examination of the influences of self-determination in the family, school, and workplace.[9] Socioeconomic status and ability are exogenous in each. Though measured at the same time as the other tenth-grade variables, they are considered prior stable phenomena. They influence tenth-grade achievement and self-esteem and the initial measures of internal motivation and control. Because of the absence of relevant data for all three time periods, there are self-determination constructs for all three periods in the school model, but for only two in the family and workplace models. The specification of direct causal influence is limited to the same or immediately contiguous time periods. For example, the effects of socioeconomic background and ability on self-esteem, measured after the tenth grade, are specified as indirect, mediated by the more proximal, relatively stable, self-image constructs.

The specification of relationships among the endogenous constructs could take a number of forms. Some statistical constraints should first be recognized. Because of multicollinearity, simultaneous estimation of both lagged and contemporaneous paths from one variable to another is hazardous. For example, if we were to specify that tenth- and eleventh-grade achievement influence eleventh-grade self-esteem, the strong relationship between these independent variables (the stability of achievement is .69 in Figure 2) could cause difficulties in parameter estimation (Gordon 1968). Second, due to the absence of appropriate instrumental variables, we do not estimate reciprocal effects.[10] As a result, in Figures 2-4 each construct is permitted to influence another only once, either through a contemporaneous or a lagged causal path, with only one-way causation.

As noted earlier, the academic achievement measures represent grades over the previous year. Intrinsic motivation and self-esteem could affect grades received subsequently, but would not influence *prior* grades. Therefore, the sense of self-determination in the family and self-esteem, both measured in the tenth grade, influence eleventh-grade achievement. However, grades received over the past year, considered as signs of competence and adaptive capacity, could influence others' granting of autonomy to the adolescent, and the adolescent's subjective perceptions of autonomy. For example, parents might allow greater independence to children who demonstrate effective problem-solving through their schoolwork. Teachers could give more challenging

assignments to students with better academic records. Past grades would also likely influence self-esteem. As a result, achievement measured in wave 1 (actually ninth-grade achievement) influences the sense of self-determination in the family and school settings in the tenth grade as well as tenth-grade self-esteem. The same rationale holds for the subsequent time period.

Of greatest interest are the interrelations of feelings of self-determination and intrinsic motivation with respect to the family, school and work, and self-esteem. These relations could be reciprocal and immediate, with intrinsic motivation influencing self-esteem and self-esteem influencing intrinsic motivation, in a dynamic ongoing process. We posit that the sense of self-determination has a contemporaneous effect on self-esteem. Assuming that perceptions of self-determination are based, at least partially, on others' actions, it is reasonable to suppose that the behaviors of persons in authority (parents, teachers, supervisors) would evolve over a period of time and be rather impervious over the short run to change in the adolescent's self-esteem. However, it is probable that over a longer period of time others' treatment would respond to change in the adolescent's self-esteem. Similarly, high self-esteem may lead one to seek out or construct complex, meaningful, and interesting activities, but it may not be possible to do so immediately.

Thus, to the extent that there is correspondence between objective situations and these subjective perceptions, we might expect lagged effects of self-image on the sense of self-determination. Prior research, using both objective and subjective measures of work experience, have generally demonstrated lagged effects of psychological dimensions on autonomy, but contemporaneous effects of autonomy on psychological variables.[11] Similarly, we posit that self-esteem has lagged effects on self-determination and immediate effects on self-esteem.

Our attention has been confined thus far to the high school period. Self-esteem one year and five years beyond high school further contribute to an understanding of self-concept development. The stability of the self-image over time indicates the degree to which earlier influences have lasting effects.

The models were estimated by maximum likelihood analysis of structural equations (Jöreskog & Sorböm 1979), using LISREL 7 (Jöreskog & Sorböm 1989). In each case, a variance-covariance matrix constituted the program input. Initially, confirmatory factor analyses were undertaken to develop the measurement models, representing each construct with items that had theoretically reasonable and substantial loadings in an exploratory factor analysis. The fact that the specified lambda-coefficients for the self-esteem and intrinsic motivation constructs remained significant and were fairly similar in magnitude across time assured us that the constructs themselves were not changing. Figures 4 to 6 are full-information models; the measurement and causal parameters are estimated simultaneously. When the same measures are repeated in multiple waves, errors in any repeated indicator may covary as a result of their shared variance or measurement effects. Thus, the models included correlated error terms of *the same* items between contiguous periods. Because we had only one indicator of grade-point average, it is assumed to be measured without error. In all figures, only the standardized parameters are presented.

Findings

THE STABILITY OF SELF-ESTEEM

The estimation and fit of our self-esteem measurement model have been extensively discussed elsewhere (Owens 1992a, 1993, 1994). Here we briefly examine the self-esteem construct across the five waves of data. First, the model fits the data well: the fit ratio is 3.43 (χ^2 = 493.65, df = 144) and the GFI is .964. The stability coefficients (or standardized betas) indicate that the construct is quite stable (see Owens 1993 for analyses showing the construct's structural invariance[12] across time). The stability of self-esteem is .62 over the first interval of the study — from the first to the second waves (18 months) — and .72 and .71 over the second and third intervals (one year each). The interval between the fourth and fifth waves increases to four years, which deflates the stability estimate to .50, yet like the other coefficients it is significant at the .05 level.

These estimates are consistent with prior theoretical and empirical work. For Erikson (1959), the establishment of identity is the critical developmental task of adolescence, after which it remains stable. The preservation of a consistent sense of self has been postulated as a major motivational goal (Epstein 1973; Korman 1970; Lecky 1945; Owens 1993; Rosenberg 1979; Swann, Stein-Seroussi & Giesler 1992). Other studies that have correlated self-image measures over time yield quite comparable estimates. Engel (1959) has estimated that self-concept stability over two-year periods during high school is .78 (corrected for unreliability). Bachman, O'Malley, and Johnston (1978), using the Youth in Transition data and a ten-item measure of global self-esteem (including our four items), presents stability estimates (corrected for unreliability) at each interval between waves of .74, .88, .89, and .69. Finally, a panel study of male students indicated a similar level of persistence for four self-concept dimensions during college (Mortimer & Lorence 1981). These findings indicate that as a construct, self-image tends to be quite stable (from adolescence onward); and, with the possible exception of a slight dip in the youngest adult years, moves on a trajectory of increased stability over the life span (see Alwin 1994).

We turn now to three causal models corresponding to the family, the school, and the workplace. Each model appears to fit the data well. In the family model (Figure 4) the fit ratio is 2.42 (χ^2 = 1595.24, df = 659) and the GFI is .921. In the school model (Figure 5), the fit ratio is 2.49 (χ^2 = 2015.12, df = 809) and the GFI is .911. Finally, the fit ratio in the work model (Figure 6) is again reasonable: 1.56 (χ^2 = 917.63, df = 587) with a GFI of .828.

THE FAMILY MODEL

It is noteworthy that the construct representing self-determination with respect to the family (Figure 4) is quite persistent (.65). (All asterisked coefficients are statistically significant, $p < .05$.) Clearly, parents' treatment of the adolescent, at least as seen through the eyes of the child, does not change radically from year to year.

Social class background has a positive effect on the perception of internal control in the family (.16), indicating a more democratic style of relationships in higher-status families (Gecas 1979). While the findings suggest that parents do

not confer greater decision-making power on children of higher intellectual ability, demonstrated achievement does matter: school achievement prior to the tenth grade has a positive effect on internal control in the family sphere (.19) in the tenth grade. By the eleventh grade, however, neither academic achievement nor the self-esteem of the child has an observable effect on the sense of self-determination, net of its stability over time.

The paths of greatest interest are those linking the sense of self-determination in the family sphere and self-esteem. The coefficient from the tenth-grade construct to self-esteem suggests that this effect is rather strong (.38), with grade-point average and ability controlled. However, because the stability of self-esteem over time is not taken into account here, the second path — from self-determination in the family to self-esteem in the eleventh grade — offers a more crucial test. This path of .13 may not seem particularly large, *but both grades and prior self-esteem are now controlled.* Adolescent experiences of internal control in the family domain thus appear to enhance self-esteem. Given the high stability of self-esteem (.79, .75, and .54 over the next three waves), this influence, though small in absolute magnitude, is likely to be persistent (Kohn & Schooler 1978).

In the mid portion of the model, the path from ability to student grade-point average in wave 1 (tenth grade) is a rather striking .62. At the same time, the path from socioeconomic background is a negative .10. It would appear that teachers, through their assignment of grades, reward ability, not social class origin (Rehberg & Rosenthal 1978; Rosenberg, Schooler & Schoenbach 1989). It should be noted, however, that the multicollinearity (.42) of the predictors could generate instability in the beta-coefficients. Whereas the zero-order correlation of the socioeconomic background and achievement (GPA) constructs is a positive .178, other research has also reported negligible relations between school grades and social class background once ability is controlled (Crouse et al. 1979; Portes & Wilson 1976; Sewell & Hauser 1975). The only significant predictor of grades in the eleventh grade is the lagged variable, and grades exhibit high stability. In the twelfth grade, self-esteem has a positive effect on grades (.08), which comports with Owens (1994).

The fact that socioeconomic background has no significant effect on self-esteem in grade ten is consistent with Rosenberg's and Pearlin's (1978) claim that it is one's own achievement, not that of one's parents, that determines self-evaluation. Also consistent with their position, both measured ability (.15) and grade-point average over the previous year (.11) have positive effects on tenth-grade self-esteem. Grade-point average through the eleventh grade (measured in wave 2) likewise influences self-esteem in the spring of grade eleven (.17). (Owens 1994 and Spenner and Otto 1985 also find that grades have positive effects on self-esteem.) However, by the end of high school, grades no longer affect the adolescent self-image. Bachman, O'Malley, and Johnston (1978) have reported the declining influence of grades over time; they attribute this pattern to a developmental effect, not to secular decline in the value of education over the period (O'Malley & Bachman 1979).

School performance (indicated here by GPA) may have little impact on twelfth-grade self-esteem (unlike that of sophomores and juniors) because of the expanded freedom and widening social activities and social comparisons

available to a graduating senior (e.g., dating, driving, working, college-hunting, preparing to enter the military, and preparing to move out on one's own). As a result, the earlier importance of high school grades as a source of self-esteem is diluted. Moreover, by the twelfth grade, the asset or liability of grades as a source of post-high-school opportunities (Owens 1992b) has, for the most part, already been felt, distancing the psychological centrality afforded high school grades.

THE SCHOOL MODEL

As Figure 5 shows, there is also a rather high stability in the intrinsic motivation to schoolwork over the high school period (both betas = .62). The consistency of school achievement (GPA) as an influence on the perception of self-directed activity in school is particularly striking. School grades in the first (.29), second (.12), and third (.14) waves foster an internal motivation for schoolwork. Apparently, students with high grades come to find schoolwork more meaningful and interesting and feel they are improving their ability to think and solve problems. At the same time, intrinsic motivation at school influences grades, as indicated by the paths of .08 and .11 over the first and second intervals.

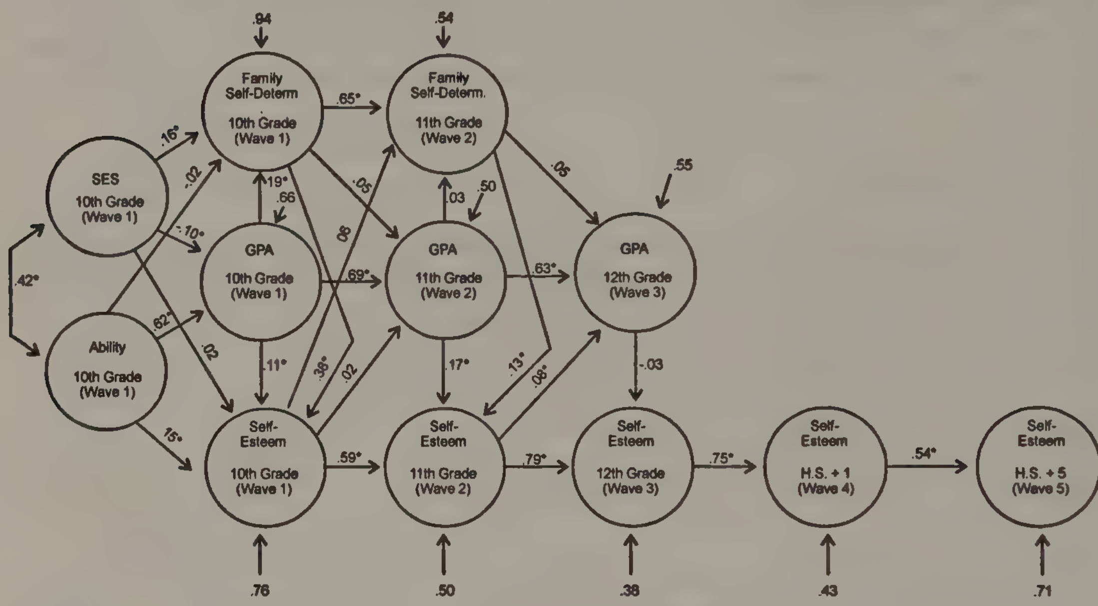
While there was little evidence that self-determination in the family setting and grades are positively interrelated, here we find a pattern of mutual influence. One might expect that a sense of intrinsic motivation and control in the domain in which grades are achieved, that of the school, would have greater significance for achievement. Unlike the family construct, intrinsic motivation for schoolwork is not affected by parental social class.[13] Moreover, student ability has no significant independent effect on intrinsic motivation in school. To the extent that intrinsic motivation is an indicator of students' experiences in the school (not simply reflections of social class and ability), it may be concluded that teachers, in promoting these experiences, respond to students' actual performances.

What are most important from our perspective are the three significant paths from the intrinsic motivation construct to self-esteem. They are manifest with ability and grades taken into account in the first period (.28), and when grades and prior self-esteem are controlled in the second (.14) and third (.16) periods. Apparently, it is not so much the achievement of high grades that enhances self-esteem; the experience of intrinsic motivation in school generally has the more consistent effect. A sense of self-initiated action and intrinsic motivation enhance the self. The fact that self-esteem has no significant effects on intrinsic motivation in school, in either interval, argues against the notion that our measure of intrinsic motivation is simply a reflection of self-esteem.[14]

THE WORK MODEL

Before describing the findings on work (Figure 6), we remind the reader that this analysis includes only students employed during *both* the eleventh and the twelfth grades. (The measures of intrinsic motivation for work were not included in the tenth-grade survey.) Intrinsic motivation for work manifests somewhat higher stability (.76) than the corresponding family and school constructs in the whole panel. However, school grades are somewhat less stable

FIGURE 4: Family Self-Determination and Self-Esteem



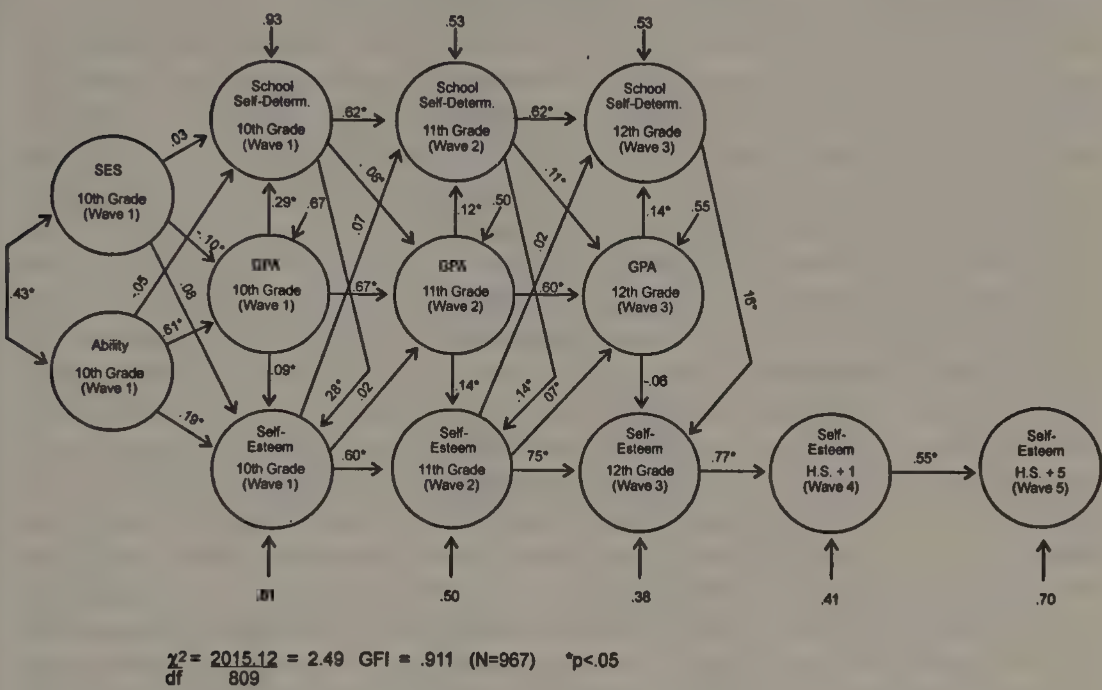
$\frac{\chi^2}{df} = \frac{1595.24}{659} = 2.42$ GFI = .921 (N=965) *p<.05

in this subgroup between the eleventh and twelfth grades (.50). And self-esteem also shows somewhat less stability through the high school period (but not thereafter), especially in the path from tenth- to eleventh-grade self-esteem (.46). These coefficients express the degree of correlational stability — the extent to which persons who have high scores during the first period, relative to their peers, retain this advantage during the second.[15]

While the differences in stability are not large, they suggest that students who continue to work while in school may experience more change.[16] Social scientists studying the life span have emphasized the importance of environmental continuity as a source of personal stability (Mortimer, Finch & Kumka 1982; Moss & Sussman 1980; Owens 1992a; Sears 1981). According to "the aging stability hypothesis" (Glenn 1980), younger people are more likely to have to adapt to new roles and social conditions; their personalities therefore are less stable (Lorence & Mortimer 1985; Owens 1992a). The adolescents in this working subgroup have recently encountered a new life domain, probably necessitating major adaptations in daily routines. The somewhat lower stability of this group in self-esteem and achievement might be expected given this new role acquisition.

The path from tenth-grade self-esteem to eleventh-grade intrinsic work motivation is positive (.33), while eleventh-grade self-esteem bears a *negative* relation to the twelfth-grade work construct (-.22). Recent developments in a bidimensional view of self-esteem as well as aspects of the principle of self-actualization help explain this seeming paradox. First, if Owens (1993, 1994) is

FIGURE 5: School Self-Determination and Self-Esteem



correct in asserting that the positive dimension of self-esteem is associated with prosocial and proactive attitudes and behaviors, then individuals with high self-esteem entering the world of work may seek — and be granted — responsibilities and input into the job unavailable to those with less favorable self-images. The result is that positive self-esteem initially increases self-determination at work. Second, as one continues on the job — as all the subjects in this subsample did — initial intrinsic motivations may subside as the constraints of adolescent work routines become manifest (nearly three-fourths of the workers were operatives, service workers, or laborers). Consequently, as one stays in the high school labor force, greater self-esteem may actually work against *subjective* feelings of self-determination on the job, thwarting high-self-esteem subjects' attempts to experience self-actualization (Maslow 1970). Finally, a form of dissonance may set in as the high-self-esteem individual — previously excited about the prospects of pitching in and having a say — exhausts the intrinsic elements and growth potential of the job, culminating in a new feeling that one's assets are not being fully utilized.[17]

We observed earlier that grades in school predicted intrinsic motivation, in the case of the family in the first period and of the school in all three periods. Here we find that achievement in school has no significant effect on intrinsic motivation at work. Moreover, an intrinsic motivation toward work does not enhance school grades. Intrinsic motivation in the work sphere, unlike that in the school, appears to be quite unrelated to school achievement. (Other analyses of these data suggest that this subjective experience of work, in conjunction with long work hours, depresses school achievement — see Finch & Mortimer 1985.)

Still, grades in school show a positive relation to self-esteem among employed students in both the tenth (.28) and eleventh (.20) grades.

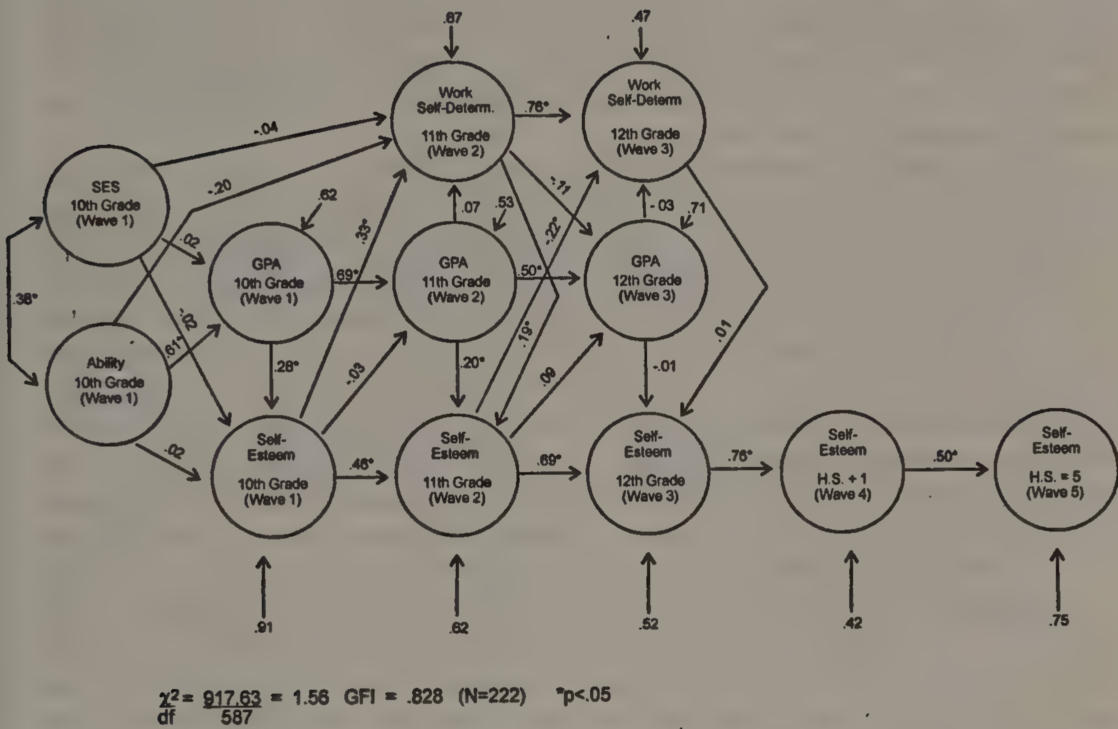
Turning finally to the paths of greatest pertinence, we observe a perplexing pattern. Intrinsic motivation toward work enhances self-esteem in the eleventh grade (.19), confirming the hypothesis that this subjective experience on the job engenders positive self-attributions and evaluations. But intrinsic motivation with respect to work is not significantly related to self-esteem in the final year in high school. Persons may be most vulnerable to change — of a positive or negative character — immediately after the acquisition of new social roles (Frese 1982; Hall 1971; Owens 1992a; Van Maanen & Schein 1979). We selected this subgroup on the basis of their work experience over two contiguous years. It is conceivable that by the second year, the immediate impact of work experience on self-esteem would have dissipated (the effect of working would then become wholly indirect — through the stability of self-esteem). To examine the evidence for this interpretation, we compared the effects of intrinsic motivation at work on self-esteem (using ordinary least-squares regression) for those who started work in the eleventh grade and those who were working in both the tenth and eleventh grades. For the first group, "new" to employment in the junior year, intrinsic work motivation had a significant effect on eleventh-grade self-esteem ($\beta = .17$, $p < .001$, with achievement and tenth-grade self-esteem controlled), while intrinsic work motivation was not significantly related to self-esteem for the veteran workers ($\beta = .08$). However, in the senior year the effects of intrinsic work motivation on self-esteem were not statistically significant for either the new workers (those working for the first time in grade 12) or the veteran workers (those who also worked in grade 11). We conclude that intrinsic motivation in the work sphere, like that in the family and school domains, can have positive implications for the self. In this panel, however, the positive effect is confined to the junior year of high school.[18]

Discussion

The limitations of this research should be remedied in the future. Regrettably, this study does not include both women and men; it is still necessary to determine whether intrinsic motivation and a sense of internal control have similar implications for self-concept development in adolescent women. The work of Miller et al. (1979; Miller 1980) suggests that adult men and women respond similarly to self-direction in work (see also Mortimer, Finch & Maruyama 1988).

A second limitation is that all constructs, with the exception of ability, are self-reported. For self-esteem, whose essence is truly subjective, such measures are optimal. Our measures of self-determination are also subjective. It is of interest to know to what extent the subjective perception of self-directed activity, what we call self-determination or intrinsic motivation, corresponds to actual opportunities for self-directed activities in the three role domains under investigation. To assess the amount of autonomy inherent in the environment, information from parents, teachers, and supervisors or other more objective data would be highly desirable.

FIGURE 6: Work Self-Determination and Self-Esteem



Third, in an attempt to simplify the causal models, we have not simultaneously assessed the effects of intrinsic motivation in the family, school, and workplace on the development of self-esteem, in the context of the same analytic model, nor have we examined the contemporary reciprocal interrelations of the sense of self-determination and self-esteem. The independent effects of experiences in these domains on the self-concept, and any immediate reciprocal causality, remain to be determined.

But in spite of these limitations, these data are consistent with the proposition that the sense of self-determination in three domains of life enhances adolescent self-esteem. Supporting Kohn and Schooler's "generalization model," and Rosenberg's "principle of self-attribution," shared decision making in the family and an internal locus of motivation in school engender positive self-evaluations. The findings were mixed with respect to the work sphere. This suggests that the intrinsic motivation toward work may have somewhat different developmental implications for adolescents (see also Finch & Mortimer 1985; Mortimer & Finch 1986a). However, longevity in teenage employment may counteract perceptions of self-determination. Nevertheless, considering all three context domains, the results of this research generally parallel a previous study of a panel of young, highly educated adult men (Mortimer & Lorence 1979b; Mortimer, Lorence & Kumka 1986) for whom autonomy was found to strengthen the sense of competence over time. Moreover, the findings confirm and extend Kohn and his colleagues' studies of a more representative panel, including the full range of age groups (16 and over) in the working population

(Kohn & Schooler 1982; Slomczynski, Miller & Kohn 1981), and both sexes (Miller et al. 1979).

There was evidence that subjective perceptions of self-direction in school, but not in the workplace, also promote academic achievement. Perceiving one's schoolwork as providing opportunities to learn, think, and solve problems consistently heightened school grades. Prior school grades also enhanced intrinsic motivation at school.

This article has focused on the interrelations of the sense of self-determination, school achievement, and self-esteem. The finding that each of these constructs is rather stable has important implications. The stability of the self-determination constructs indicates considerable continuity in adolescent experiences in the family, at school, and at work. The stability of achievement and self-esteem suggests that we may have to look elsewhere, to early adolescence or even to childhood, to identify the most crucial formative experiences.

Most past studies have examined socialization and development in each life stage as a distinct process; there are literatures on infancy, childhood, adolescence, adulthood, and old age (Mortimer & Simmons 1978). The present research suggests the fruitfulness of an alternative perspective on the life course. The same kinds of experiences that have been found to stimulate positive psychological outcomes in adulthood — personal discretion in decision making, a sense of self-determination, interesting and challenging tasks — also foster self-esteem in the adolescent years. But studies of adults are generally confined to the domain of work. Here we find that the sense of self-determination, a probable subjective outcome of autonomy, has consequences for the self when it is encountered in other social contexts, in the family and at school, as well as in the workplace. The findings suggest that autonomy has important implications for human development (Bronfenbrenner 1979), though it may be expressed in different ways in different periods and domains of life. They indicate that there are gains in considering the life course as a whole, so that the insights developed from research on one phase can enlighten investigations of others.

Notes

1. In a broader sense, Woelfel and Haller (1971) argue that the role of the "self-reflective act" in attitude formation (including attitudes about the self) is more potent than interpersonal influences when the "object of the attitude is unambiguous and observable" (76).

2. We can place our investigation of self-determination's relation to self-esteem in the broader literature on the relation of perceptions of self-control to general well-being (e.g., social, psychological, and physical). For example, using a longitudinal sample of Depression-era youths, Clausen (1993) finds that planfully competent adolescent males, who also have a higher sense of personal control and self-determination, have greater psychological and physical well-being, smoother interpersonal relationships, fewer recurrent life crises, and less failure and frustration in later life than their less competent peers. Such related perceived control concepts as self-efficacy (Bandura 1989), locus of control (Strickland 1989), and personal control (Rodin, Timko & Harris 1985) have been linked to such important outcomes as health, sports, school, work, marriage, and general life satisfaction (also see Skinner 1995).

3. It has also been shown that perceptions of greater control in the classroom lead to a variety of positive school outcomes, such as increased effort, attention, and participation, as well as improved self-regulatory strategies (Berry & West 1993; Skinner 1995).

4. According to Condry (1977:472), "the outcomes of intrinsically motivated activity are encoded as more self-relevant and thus internalized more than the outcomes of extrinsically motivated activity, where the role of the self is more passive."

5. Overall cumulative attrition by wave was 14.8% for wave 2, 18.7% for wave 3, 26.8% for wave 4, and 26.4% for wave 5. Attrition comparisons between the 291 blacks and the 2,177 whites are wave 2, 13.4% for whites and 17.5% for blacks; wave 3, 17.9% for whites and 18.6% for blacks; wave 4, 25.3% for whites and 30.2% for blacks; and wave 5, 29.5% for whites and 46.4% for blacks.

6. Excluding persons with missing data led to the loss of 627 cases (37% of the 1,681 white respondents in the fifth wave). To ascertain the differences between them and the other respondents, a series of t-tests was performed, using additive construct scores. There were no significant differences between persons with no missing data and those with missing data (on any other variable) in socioeconomic background, family autonomy at time 2, or self-esteem after the tenth grade. Respondents with missing data were lower on ability; on family autonomy at time 1; on school autonomy at times 1 and 2; on achievement at times 1, 2, and 3; and on self-esteem in tenth grade. These differences are cause for concern. But pairwise deletion also introduces an indeterminate amount of error, because the entries in a data matrix are not based on the same cases. Moreover, covariance matrices based on incomplete data are often ill-defined and occasionally not positive definite. The most obvious problem is choosing the appropriate standard deviations (SD). In computing the correlation or the covariance of the variables j and k, when some data are missing it is not the case that SD_j is constant for all pairs (SD_j, SD_k). While various proposals have been advanced to alleviate this problem, we conservatively limit the analysis to cases without missing data (Bollen 1989).

7. We report the χ^2/degrees of freedom ratio (fit ratio) and the goodness-of-fit index (GFI). The fit ratio generally should not exceed about 3 to 5. A nonsignificant fit ratio indicates that the variance-covariance matrix derived from the theoretical model is similar to the observed variance-covariance matrix, as one would hope. The GFI shows the amount of variance and covariance explained by the model, and ranges from 0 (no account) to 1 (perfect account). A value in the range of .9 is generally acceptable, although there is no clear consensus on the cutoff (Jöreskog & Sorböm 1989).

8. Deci, Eghrari, and Patrick (1994) suggest that self-determination and intrinsic motivation are essentially equivalent concepts, giving us confidence that our measure of self-determination in the school is appropriate.

9. Since the self-determination constructs involve three separate domains and different actors (parents, teachers, and supervisors), they are conceptually distinct. Empirically, they are only moderately intercorrelated. (In grade ten, the correlation between self-determination in the family and at school, using unit weighted indices, is .30; in grade eleven, it is .27 between family and work and .25 between school and work.) An exploratory analysis (principal factor) including the family and school items yielded two distinct factors corresponding to each domain in the tenth and eleventh grades.

10. Because we do not include reciprocal effects, our analyses could overestimate the one-way effects.

11. We believe that the models are justified on conceptual grounds (Mortimer & Lorence 1979a, 1979b) and on the basis of prior empirical work (Kohn & Schooler 1978, 1982, 1983; Lorence & Mortimer 1985; Mortimer & Finch 1986a). Still, an alternative causal ordering of the variables cannot be ruled out.

12. Structural invariance is present when the dimensions of a construct are the same across time and when the pattern of relationships among its measured attributes persists across waves.

13. In contrast, Miller, Kohn, and Schooler (1982) report that parental socioeconomic status has a positive effect on educational self-direction, as indicated by the substantive complexity of schoolwork and closeness of teacher supervision.

14. A replication of this model using an alternative self-depreciation construct shows that GPA has no causal effect on self-depreciation, while self-depreciation engenders lower grades (-.08 and -.09 for the paths from tenth to eleventh and from eleventh to twelfth grade, respectively). Exploring the alternative self-depreciation models further, we note that the relation of wave 1

self-determination in the family to wave 2 self-depreciation = -.35 ($p < .05$) and of wave 1 self-depreciation to wave 2 self-determination in the family = -.08. Self-depreciation's relationship to school self-determination is wave 1 school to wave 2 self-depreciation = -.32 ($p < .05$), wave 1 self-depreciation to wave 2 school = -.02; wave 2 family to wave 2 self-depreciation = -.13 ($p < .05$), and wave 2 self-depreciation to wave 3 family = -.01. For the workplace model the relationships are wave 1 self-depreciation to wave 2 work = -.39 ($p < .05$); wave 2 work to wave 2 self-depreciation = -.09; wave 2 self-depreciation to wave 3 work = -.07.

15. Another way of conceptualizing stability is by level change (Mortimer, Finch & Kumka 1982). Using this criterion, both employed and unemployed students increased in self-esteem over time.

16. However, when the family and school models were reestimated for this working subgroup, intrinsic motivation in both family and school manifested levels of stability that were almost identical to those in the whole panel.

17. Another paradox occurs when we see some evidence for the first time that ability and an intrinsic motivation construct may be negatively correlated ($\gamma = -.20$). (Although the t-value of 1.9 is just below the conventional cutoff of $t = 1.96$ for $p < .05$, given that this subsample's N of 222 is less than one-quarter the size of the other two models, this gamma-coefficient is interesting.) Why would the less able students feel more internally motivated in their jobs? The picture becomes clearer when we consider the difference in time working by student ability. Students of lower ability were working longer hours (the correlation of ability to hours is a negative .28 in the eleventh grade). Given their greater time involvement in the work sphere, the less able students may actually have the more responsible jobs. On the average, the eleventh- and twelfth-grade students (who were employed in both the junior and senior years) were working approximately twenty-four hours per week.

18. Shanahan et al. (1991) found a positive effect of decision-making autonomy on high school students' depressive affect, indicating that novice workers find independence somewhat unnerving.

Abstract

This study examines the interrelations of work experiences and occupational values in a panel of 1,000 ninth-graders followed over a four-year period. Neither employment itself nor hours of work had substantial effects on occupational value formation. However, the opportunity to learn useful skills at work was a consistent positive influence on increasingly stable intrinsic and extrinsic value dimensions. We conclude that the central finding of research on work and adult psychological functioning — that the conditions of work are what matter — can be generalized to adolescents.

Given that work values are important determinants of vocational choice (Davis 1965; Mortimer 1974) and actual occupational destinations (Mortimer, Lorence & Kumka 1986), it is important to understand their origins. This article addresses a potentially important, but thus far neglected, influence — adolescent work experience. American teenagers increasingly hold part-time jobs while attending school (Manning 1990). Because adolescence is a crucially important period for the formation of vocational interests and identity (Erikson 1968), it is reasonable to suppose that work experience would have a significant formative influence on adolescents' thinking about the potential rewards to be obtained from work.

Steinberg et al. (1981) posit three possible consequences of adolescent employment for vocational socialization. First, part-time jobs may help adolescents to acquire attitudes, values, habits, and knowledge that make them

** This article was presented at the 1992 meeting of the American Sociological Association. better adult workers. In contrast to this "competence model," the "cynicism model" proposes that since jobs available to teenagers are often menial, employed youth become cynical about work and focus on its extrinsic rewards. The third plausible hypothesis is that early work experience has no meaningful influence because teenagers view their jobs as temporary and do not expect to engage in similar work after completing school. Steinberg et al.'s (1981) finding, that part-time employment had little association with occupational values among 531 tenth- and eleventh-grade California high school students, supports the no-influence hypothesis.

Research on adults shows that the *conditions of work* are what matter for psychological development (Kohn & Schooler 1983; Mortimer, Lorence & Kumka 1986). If the findings of such research are applicable to younger workers, we should examine the quality of adolescents' work as well. However, past research on the psychosocial impacts of adolescent work experience has given far more attention to employment status (employed versus not) and to the intensity (hours) of work than to the quality of work. (For exceptions, see Stern et al. 1990; Wijting et al. 1977).

Given the paucity of research on the quality of adolescent work as a factor in occupational reward value formation, we look to studies of young adults for guidance. In Mortimer and Lorence's (1979) research on a panel of male college graduates, high levels of economic reward enhanced the valuation of extrinsic rewards. In this study, and in Lindsay and Knox's (1984) replication with a national sample of high school seniors, high monetary remuneration fostered declines in intrinsic values, while autonomous and challenging work strengthened intrinsic values over time.

However, Mortimer, Dennehy, and Lee (1991) find that self-direction at work has no significant relation to adolescent occupational values. Then what qualities of youth jobs might make a difference? In anticipating their adult "possible selves" (Markus, Cross & Wurf 1990), adolescents may be particularly responsive to occupational experiences that augur successful role adaptation, such as the acquisition of general proficiencies or skills. Being able to help others may also foster a satisfying sense of movement toward adult status, increasing the adolescent's sense of usefulness and competence.

In contrast, it is reasonable to suppose that work offering high levels of extrinsic reward (e.g., good pay) would foster extrinsic work values. Stressors in the workplace (House 1980; Kahn 1981; Kohn & Schooler 1983) could also foster an extrinsic orientation toward work. That is, if a young person's work experience is punishing, work may come to be seen not as providing intrinsic gratifications of value in itself, but only as a source of income and instrumental benefits.

Among adults, prior occupational values have been found to influence the selection of work, including the extent of autonomy, income, and social content (Lindsay & Knox 1984; Mortimer & Lorence 1979). However, there is reason to expect divergence in such person-job dynamics in this younger group, for whom occupational values may have less salience and motivational force. Moreover, because adolescents have a narrow array of work opportunities, concentrated in the retail and service sectors and, in the earlier years of high

school, in informal work, they may not be able to select jobs that are congruent with their values.

In addition to examining the relations between work and occupational values, we assess differences related to social background and gender. Adults in more advantaged social positions (i.e., white and of high educational and occupational attainment) have been found to be more intrinsically oriented; the less advantaged emphasize extrinsic values (Quinn, Staines & McCullough 1974; Shapiro 1977). Similar patterns have been observed among adolescents (Krau 1987; Lindsay & Knox 1984; Mannheim 1988). In fact, the effects of socioeconomic standing and race on occupational values may grow stronger over time, as adolescents make choices regarding academic curriculum that influence future occupational options. Parents and adolescent children may become increasingly involved in discussions about work, at which time parents transfer their work values to their children, especially when they have close, communicative relationships (Mortimer & Kumka 1982).

While the literature yields mixed findings on gender differences in occupational values, some studies show that men are more concerned with autonomy and the extrinsic benefits of jobs, whereas women emphasize more intrinsic concerns, such as having interesting work, opportunities to help others, and good interpersonal relationships (Mortimer & Lorence 1995). But because gender role norms are changing along with women's labor force behavior, contemporary boys' and girls' orientations to work may be more similar than in previous cohorts (Hanson 1988; Lueptow 1980). We also include grade-point average in the analysis.

Data Source

The data were obtained from a four-year longitudinal study (1988-91) of the effects of adolescent work experience on mental health and vocational development. The panel was chosen randomly from a list of ninth graders enrolled in the St. Paul (Minnesota) School District. A probit analysis of the census tract characteristics of general sample participants (64% of eligible cases) and those who chose not to participate indicated that the panel is representative of students attending the St. Paul schools (Finch et al. 1991; Mortimer et al. 1992).

Self-administered questionnaires were distributed in school classrooms each year (grades 9-12); students not present for either of two scheduled administrations (and those not attending school — 10% in wave 4) were mailed questionnaires, using procedures recommended by Dillman (1983). Of the initial 1,000 participants, 93% were retained over the four-year period.

MEASURES

In each wave the adolescents were asked, "In the future, how important do you think each of the following will be to you when you are looking for a FULL-TIME job?" Students rated specific features of work on a four-point scale, ranging from not at all important to extremely important. Four items reference extrinsic values: income, advancement opportunity, security, and prestige. Intrinsic values refer to the use of skills and abilities; learning opportunities;

autonomy and responsibility; and the chance to work with, and be helpful to, other people (see Appendix A). Confirmatory factor analyses showed that a two-factor model, with intrinsic and extrinsic dimensions, provided a good fit to the data in separate analyses for boys and girls in each grade (fit ratios, i.e., chi square divided by the degrees of freedom, ranged from 2.69 to 4.43; GFIs ranged from .936 to .966). Multiple group comparisons showed that the measurement structure for boys and girls was substantially the same.

The opportunity to obtain skills on the job and job stressors are latent variables defined by multiple indicators; income evaluation[1] and work with people are based on single indicators (see Appendix A). The analyses also include gender (coded 1 if male, 0 if female), race (coded 1 if white, 0 if other), grade-point average, and socioeconomic status (a composite of standardized measures of parental education and family income).

Findings

EMPLOYMENT STATUS, INTENSITY, AND OCCUPATIONAL VALUES

Both boys and girls have substantial work experience during high school. Forty percent of boys were employed in grade 9 in comparison to 63% of girls. The percentage of employed boys increased to 58% by wave 4; girls' employment rate increased to 70%. Ninth-grade boys and girls who had jobs both worked, on the average, about 11 hours per week. By the fourth wave, work intensity also increased for both — to 22 and 20 hours respectively.

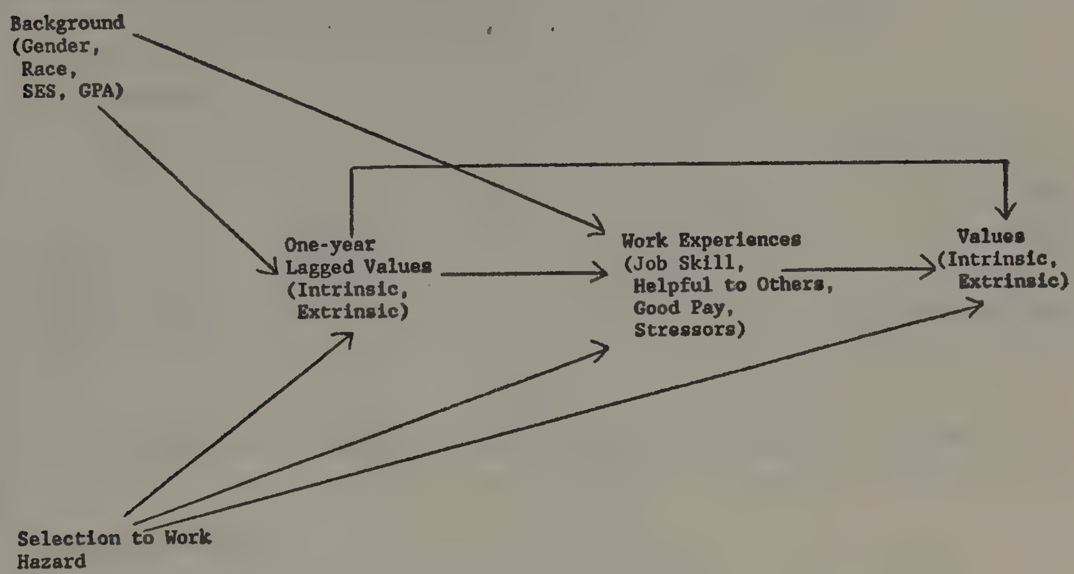
Using indices based on summations of the unweighted value items, we found no differences in intrinsic and extrinsic values, in any year, between boys who were employed and those who were not. Employed girls in grade 9 had stronger ($p < .01$) intrinsic values than their unemployed counterparts; and in wave 4, they had both higher mean intrinsic ($p < .01$) and extrinsic values ($p < .05$). There were no significant differences, by employment status, in girls' values in waves 2 and 3. Finally, neither intrinsic nor extrinsic occupational values were significantly correlated with hours worked in any wave for employed boys or girls.

Thus, there is no consistent evidence that the mere fact of employment during high school fosters distinct intrinsic or extrinsic occupational values. What evidence there is suggests that working may be associated with a higher rather than a lower intrinsic value orientation for girls. That is, in two of the four waves of data collection, girls who were employed placed greater emphasis than girls who were not employed on the inherent features of work, such as autonomy and having opportunities to use skills, learn new things, and work with people. There is no evidence that work intensity, the number of hours worked per week, influences occupational value formation.

MULTIVARIATE ANALYTIC STRATEGY

The hypothetical model shown in Figure 1 parallels those estimated by Lindsay and Knox (1984) and Mortimer and Lorence (1979). We hypothesize that the work conditions contemporaneously influence occupational values (Kohn &

FIGURE 1: Hypothetical Model



Schooler 1983; Mortimer, Lorence & Kumka 1986), while one-year lagged intrinsic and extrinsic values influence subsequent work experiences. Finally, the stability of intrinsic and extrinsic value constructs over time is tested.

There are three background variables whose influences on the value and work constructs are explored. We estimate the effects of gender,[2] race, socioeconomic status, and grade-point average on the one-year lagged values and work experience. A selection-to-work hazard rate influences all endogenous variables. If the determinants of employment were systematically related to occupational values or to work features, estimates could be biased if these bases of selection were not taken into account (Berk 1983). Therefore, three probit analyses were used to predict employment each year, with gender, age, race, family composition, socioeconomic status, and an indicator of the propensity to work[3] as predictors. These variables are temporally prior to both work experiences and values at each wave. Separate hazard rates, reflecting these predictors, are used to control selection to work at each wave (Heckman 1976, 1979).

This model is estimated three times, considering first the process of value formation between waves 1 and 2, second between waves 2 and 3, and finally between waves 3 and 4. In this way we explore developmental trends in occupational values and work experiences as students move through high school. Because different individuals work at each time, we do not attempt to model value development with the same cases over the entire period of study.

Latent variable measurement parameters and causal parameters are estimated simultaneously. While there is some variation in measurement parameters across equations, differences are slight. To indicate the relative importance of items for each construct, standardized lambda coefficients for second-wave latent variables are given in Appendix A. To simplify the models,

Table 1 to facilitate comparisons across years. Each model represents a good fit to the data, with chi square values divided by the degrees of freedom of 1.82, 1.99, and 1.89 for each period, respectively.

WORK VALUES AND EXPERIENCES

Most striking is the consistent positive effect of the construct we call job skills, signifying opportunity to learn skills on the job that are useful in the future, on the intrinsic value dimension (see Table 1, panel C). When adolescents perceive their jobs as allowing them to move forward on their occupational trajectories — enabling them to learn how to accept responsibility, get along with people, be on time, manage money, and follow directions — they come to view the

intrinsic benefits of work as more important. Of three tests of this effect, all coefficients are positive and statistically significant. However, the effect of job skills on intrinsic values decreases after wave 3 ($z = 1.94$, $p < .10$).

Given that we control the substantial stability of values, the findings provide convincing evidence that the opportunity to acquire skills on the job strengthens adolescents' intrinsic orientation toward work. Moreover, the effect of job skill acquisition extends beyond intrinsic values to influence the extrinsic construct as well. Significant positive coefficients, of similar magnitude, are evident in all periods. Lindsay and Knox (1984) likewise report what they call a crossover effect of intrinsic work features on extrinsic values.

With respect to the other work conditions, having opportunity to be helpful to others positively influences intrinsic values in the first wave; it has no significant effects subsequently. Also, only in the first wave does work stress have a significant positive effect on extrinsic values. Thus, there is a tendency, in just one period, for younger workers who experience more stress on the job to come to view work as a source of extrinsic occupational rewards. Pay has no significant impact on extrinsic values.

It could be argued that even though we have controlled prior values in estimating the effects of work, there are contemporaneous processes of reverse causation that are not taken into account. For example, persons with higher levels of intrinsic values could perceive their jobs as offering more opportunities to develop their skills. They might also mold their jobs so as to realize their values.

Because of a lack of adequate identification, we were unable to assess all pertinent reciprocal effects. However, we did estimate several models specifying reciprocal causal pathways. They provided no evidence for a pattern of reverse causation. Paths from wave 2 intrinsic values to wave 2 job skills and helpfulness, and likewise from extrinsic values to stressors, were not statistically significant. The path from wave 4 extrinsic values to job skills was also insignificant. We were unable to estimate the effects of instrinsic values in waves 3 and 4 on contemporaneous job skills because of poor model identification.

Consistent with our speculation that adolescents are unlikely to be able to choose their work on the basis of their values, given the relatively small selection of jobs from which they have to choose, wave 1 occupational value orientations have no significant effects on wave 2 work experiences (see Table 1, panel B). However, this situation changes as adolescents mature.

Wave 2 intrinsic values have a significant, positive effect on the report the following year that one's job enables the development of useful skills; this pattern is replicated one year later. Intrinsic values measured in wave 2 also significantly predict wave 3 opportunities to be helpful to others, although this effect is not repeated in the final period. Statistical comparison of coefficients representing the effects of lagged intrinsic values on subsequent opportunities to develop job skills shows a significant change between waves 1 and 2. However, the coefficients do not significantly increase after the second period.[4]

It is somewhat anomalous that intrinsic values in wave 3 also have a positive effect on wave 4 work stressors. Some characteristics that make work intrinsically rewarding (e.g., responsibility and self-direction) may also be

stressful to occupational newcomers (see Shanahan et al. 1991). The more intrinsically motivated adolescents may steer themselves toward work that is challenging but also more stressful. Extrinsic values, however, were found to have no bearing on subsequent work experiences.

Also noteworthy is the increasing net stability of occupational values over the high school years. The unstandardized stability paths for extrinsic values rise from .520 ($p < .001$) between waves 1 and 2 to .694 ($p < .001$) between waves 3 and 4 (see Table 1, panel C), with stability in the last period marginally greater than in the first period ($z = 1.88$, $p < .10$). Intrinsic value stability significantly increases between the first and second periods only ($z = 2.24$, $p < .05$).

THE EFFECTS OF BACKGROUND VARIABLES ON WORK VALUES

Whereas boys are less intrinsically oriented than girls in all periods, there are no gender differences in extrinsic values (see Table 1, panel A). There are no significant differences between the racial categories in values.

There is a tendency for socioeconomic background to be more positively related to adolescents' intrinsic values in the latter than in the earlier periods of study. It manifests no significant influence in wave 1 but has significant positive effects on intrinsic values in wave 2 and also in 4 ($\beta = .046$, $\beta = .141$, $p < .001$, not shown), controlling race, gender, GPA, and the selection-to-work hazard. (Although the effect of SES on intrinsic values in waves 2 and 4 is statistically similar, both are significantly different from wave 1, with $z = 2.21$ and 2.82 respectively). With the same controls, social class background bears a significant, negative relationship to third-wave extrinsic values, but insignificant relationships in waves 1 and 2 (and wave 4, not shown).[5] GPA has no consistent effect on occupational values.

Positive residual correlations between the intrinsic and extrinsic value factors in each period indicate that adolescents who have higher intrinsic orientations are also the more extrinsically oriented (see Table 1, panel D). Jobs offering opportunities for skill development and to help others also appear to go together.

Summary and Conclusions

Little attention has been given in prior research to the effect of adolescent conditions of work — as opposed to the fact of work or its intensity — on the formation of occupational values. We do not find that work status itself, or the intensity of adolescent work, have consistent effects on occupational value formation. But there is substantial grounding for the conclusion that the quality of adolescents' jobs, particularly the challenges and demands that enable the development of skills, influences intrinsic and extrinsic work values. We conclude that the central finding of research on the effects of work on adult psychological functioning — that the conditions of work are what matter — can be generalized to adolescents.

In terms of the three models noted earlier — competence, cynicism, and no influence of work on values — our analysis supports a competence model.

Despite being employed largely in jobs of low status and complexity, adolescents still gain a sense of appropriate developmental progress from learning new skills, sufficient to develop stronger intrinsic value orientations. Opportunities to develop job skills fostered stronger extrinsic values as well.

It is only among tenth-graders that the chance to be helpful to others reinforces intrinsic work orientations, and that work stressors show a tendency to foster extrinsic values. Opportunities to be helpful may be considered markers of the transition to adult roles, or "possible selves," which foster positive attitudes toward work and intrinsic occupational values. Stressors may have less impact on occupational value formation as the adolescent learns to cope with them, through experience in jobs that hone their work skills. Job skills continue to strengthen both intrinsic and extrinsic values across time. It may be that both intrinsic and extrinsic benefits are seen as increasingly within reach given successful learning and adaptation to the demands of adolescent work.

However, there appears to be a developmental pattern in the effect of job skills on intrinsic value formation. While the effect is significant in all three periods, it significantly decreases after wave 3. Similarly, there are diminishing effects of helpfulness and stress on values after wave 2. As values become a more enduring characteristic of the individual, work characteristics may play a decreasing role in their articulation, though the process is by no means finished in high school. Still, the job skills index has an unchanging effect on extrinsic values over the period studied.

There are indications of an emergent relationship between social class background and values. While our analyses partially support a link between more advantaged socioeconomic status, stronger intrinsic values, and weaker extrinsic values, there are no value differences by race. Girls are found to be more intrinsically oriented. The absence of a gender difference in extrinsic values may result from social change in gender norms. Alternatively, gender differences in the development of extrinsic values may appear only later in life.

Our findings thus suggest developmental dynamics such that the relations among values, work experiences, and individual differences become increasingly similar to those manifest among adults as adolescents move through high school. As hypothesized, values that the youngest adolescents hold have no significant effect on subsequent work characteristics. In the earliest transition to work, job conditions are not significantly affected by adolescents' values about work. However, as they move through high school, young people's intrinsic values increasingly shape the kind of work they do, at the same time as they are presented with greater job choices.

Adolescents' occupational values also become significantly more stable across time. Previous research (Lorence & Mortimer 1985; Mortimer, Finch & Maruyama 1988) has documented the greater stability of other work orientations (i.e., job involvement and job satisfaction) in older workers, as compared to those who are younger (age 16-25). This pattern was attributed to processes of "aging stability": because of distinct environmental pressures and developmental processes, attitudes stabilize with age. (See Alwin, Cohen & Newcomb 1991 for similar findings with respect to political attitudes.) However, this research demonstrates that a pattern of "aging stability" in occupational values extends to the youngest workers.

APPENDIX A: Measures[a]

Extrinsic Value Construct

- Good pay (.281)
- Good chances of getting ahead (.386)
- A steady job, with little chance of being laid off (.446)
- A job that people regard highly (.454)

Intrinsic Value Construct

- A job that uses my skills and abilities (.449)
- A chance to learn a lot of new things at work (.463)
- A chance to make my own decisions at work (.500)
- A job where I have a lot of responsibility (.512)
- A chance to be helpful to others or useful to society[b] (.416)
- A chance to work with people rather than things[b] (.485)

WORK EXPERIENCES

Job Skills

- How much has your job helped you to develop the following abilities? (1 = not at all, to 4 = a great deal)
- To follow directions (.595)
- To get along with others (.638)
- To be on time (.736)
- To take responsibility for your work (.705)
- To manage your money (.456)
- Do you think that the things you are learning in your job will be useful to you in your later life? (1 = not at all useful, to 4 = extremely useful) (.421)

Helpful to Others

- My job gives me a chance to be helpful to others (1 = not at all true, to 4 = very true).

Pay Evaluation

- Would you consider your pay "good pay" for the work you do? (1 = no, the pay is not good, to 4 = yes, definitely)

Stressors

- Response categories for the first five items: 1 = not at all true, to 5 = very true
- I have too much work to do everything well (.821)
- My job requires that I work very hard (.883)
- I feel drained of my energy when I get off work (.574)
- How often is there time pressure on your job? (1 = never, to 5 = almost always) (.798)
- How often are you exposed to excessive heat, cold, or noise at work? (1 = never, to 5 = almost always) (.727)

[a] Standardized lambdas, estimated simultaneously with the causal parameters, are given in parentheses for each multiple-indicator latent variable construct, measured in grade ten.

[b] The residuals of these items, indicating people-oriented concerns, were significantly related; the unstandardized covariance is .158 ($p < .001$).

By continuing to follow this panel as it makes the transition to adulthood, we will be able to examine the dynamics of change in values following high school in response to work and other experiences, and the effects of occupational value orientations on actual attainments in early adulthood.

Notes

1. There is evidence that evaluation of income has a stronger impact on work orientations than actual income (Gruenberg 1980; Janson & Martin 1982; Jencks, Perman & Rainwater 1988; Mortimer et al. 1988). However, Lindsay and Knox (1984) report a negative effect of income on intrinsic values, and Mortimer and Lorence (1979) find that high income fosters extrinsic values. Of 16 correlations of hourly pay and values (2 values, 2 genders, and 4 waves) only one was statistically significant. In wave 4, girls with higher wages expressed stronger extrinsic values ($r = .12$, $p < .05$). However, this relationship became statistically insignificant with the lagged variable controlled.

2. Because prior analysis showed that the process of work value development was essentially the same for boys and girls (Mortimer, Dennehy & Lee 1991), the models were based on a variance-covariance matrix for all students.

3. The propensity to work was indicated by the age of starting one's first job. For students who never worked, the current age was assigned.

4. Coefficients were compared statistically using a z test, where $z = (B1 - B2)/(SE^2_{B1} + SE^2_{B2})^{1/2}$. Z scores comparing the effects of lagged intrinsic values on job skills are 2.06 (waves 2 and 3), 2.77 (waves 2 and 4), and .58 (waves 3 and 4).

5. Given this pattern, it could be argued that socioeconomic status should be controlled when assessing the effect of work on values. Therefore, we freed the parameters from socioeconomic status to the later value constructs in each model. Socioeconomic status did have significant effects on intrinsic values in waves 2 and 4. However, because none of the effects of the work experiences on intrinsic values was altered, we retained the original, simpler model specification.

Demographic, Socioeconomic, and Behavioral Factors Affecting Ethnic Mortality by Cause*

Abstract

This article examines ethnic differences in total and cause-specific mortality. We employ the linked National Health Interview Survey-National Death Index (NHIS-NDI) to examine ethnic differences in mortality from a combination of demographic, socioeconomic, and health characteristic perspectives. We find that Asian American mortality is low in part because of healthy behaviors and socioeconomic advantages; that Caucasian American mortality is higher partly because of high prevalence and quantity of cigarette smoking; and that Mexican, Native, and African American mortality is higher partly from socioeconomic disadvantages. These results give us added insight into the demographic, social, and health mechanisms that lead us to persevere or to perish.

Most mortality research has focused on how demographic characteristics — age, sex, and ethnicity — affect total and cause-specific mortality. But to properly conceptualize the multiple and interacting proximate determinants of mortality by ethnicity, researchers must extend the traditional demographic framework of mortality analysis to a more complete, though more complex, multivariate model that also incorporates social characteristics — marital status, education, and income (see Mosley & Chen 1984; Rosenwaike 1988). Moreover, health behaviors have cultural dimensions and therefore can also affect ethnic differences in mortality. A new file, the linked National Health Interview Survey-National Death Index (NHIS-NDI), allows us to disentangle some of the effects of demographic, socioeconomic, and behavioral health characteristics on ethnic differences in total and cause-specific mortality.

 Social Forces, June 1996, 74(4):1419-1438

Ethnicity (defined here broadly to include race and nationality characteristics — see Cooper 1991, 1994) is a fundamental demographic determinant of mortality. In the important ongoing debates over the measurement of ethnicity in relation to health outcomes (Cooper 1991; Crews & Bindon 1991; Williams, Lavizzo-Mourey & Warren 1994), we move away from the biological connotations of race and ethnicity to concentrate on the social significance of group membership (Dressler 1993). Thus, our research focuses on the broad range of factors that make ethnicity a powerful and socially meaningful concept in mortality research (Hummer 1996; Williams 1990; Williams, Lavizzo-Mourey & Warren 1994). By including in this study a wide range of covariates — demographic, socioeconomic, social relations, and health behaviors — of largely social character, we can capture some of the social significance of ethnicity and determine how variables within each set act as mechanisms by which ethnicity influences the mortality of individuals.

Demographic Perspective of Ethnic Differences in Mortality

Scholars have long acknowledged that ethnic differences in mortality are affected by age, sex, and medical cause of death. Life expectancies by ethnicity reveal marked differences. In 1980 Asians displayed the highest life expectancy, 82, which was even higher than that of Caucasian Americans, 74 (see Barringer, Gardner & Levin 1993). Mexican American life expectancy is similar to that of Caucasian Americans. Native American life expectancy, 71, is intermediate between that of Caucasian Americans and that of African Americans, at 68 (Rogers 1996; Snipp 1989). Although African American life expectancy lags behind that of other ethnic groups, it has increased the most dramatically from the turn of the century through the mid-1980s (Rogers 1996).

Variations in age-specific mortality rates suggest that some apparent differences may be partly a function of methodological problems. For example, Native Americans have lower life expectancy than Caucasian or Asian Americans, but lower age-specific mortality rates than Caucasians at ages 45 and above and lower than Asians at ages 85 and above. These low Native American age-adjusted mortality rates are most likely underestimates, reflecting a 45% increase in the reported Native American population between 1980 and 1990 and that in turn reflects the increased propensity for individuals to identify themselves as Native American (NCHS 1994b). The black/white gap in life expectancy is not consistent at all ages; instead, it is generally larger at lower ages and smaller at higher ages (Sorlie et al. 1992), and may even cross at the highest ages (Nam 1995).

Ethnic variations in mortality also result from differences in cause of death. Compared to Caucasians, Asians exhibit lower mortality for almost every cause of death, including death from cancer, human immunodeficiency virus infections (HIV), firearms, and motor vehicles (Fingerhut, Jones & Makuc 1994; NCHS 1994b). NCHS (1994b) has reported that compared to Caucasians of similar ages, homicide rates are lower for Asians at ages 15-24 and 25-44, although slightly higher for Asians at ages 45-64. Asians achieve their superior

life expectancies through reductions in both degenerative diseases and external causes.

Although overall Mexican American mortality is similar to that of Caucasian Americans, it results from different causes. Compared to Caucasian Americans, Mexican Americans are generally less likely to die from several of the major causes of death, including heart disease, cerebrovascular disease, cancer, pneumonia and influenza, suicide, and chronic obstructive pulmonary diseases and allied conditions (COPD); they are generally more likely to die from diabetes, homicide, cirrhosis of the liver, and HIV (NCHS 1994b).

Compared to Caucasians, Native Americans are less likely to die from cardiovascular diseases, cancer, and COPD, but more likely to die from diabetes, social pathologies, and infectious diseases. Historically, infectious diseases have been a major cause of death for Native Americans, whose tuberculosis rate is ten times as high as the rate for Caucasian Americans (U.S. Dept. of Health and Human Services [HHS] 1993). But now accidents and violence have replaced infectious diseases as major causes of death among Native Americans.

Compared to Caucasian Americans, African Americans die at higher rates from most causes of death, including circulatory diseases, cancers, respiratory diseases, infectious diseases, diabetes, homicide, and accidents (Kochanek, Maurer & Rosenberg 1994). Although most researchers have found that African Americans are less likely than Caucasian Americans to die from suicide, some studies indicate that figures for suicides are underestimated more often for African than Caucasian Americans (see Warshauer & Monk 1978). And compared to Caucasian Americans, African Americans are more than three times as likely to die from HIV and over six times as likely to die from homicide (Fingerhut, Jones & Makuc 1994; NCHS 1994a).

Social Characteristics Perspective

Ethnic patterns in mortality may reflect variability in a host of complex social and economic characteristics (Frisbie & Bean 1978). African Americans lag behind Caucasian Americans in life expectancy partly because African Americans are more likely to be in disadvantaged social categories. For instance, compared to Caucasian Americans, African Americans are less likely to be married, employed, or wealthy, characteristics that have been shown to be associated with lower mortality (Potter 1991; Schoenborn 1986). When only demographic variables are considered, compared to Caucasians, African Americans have higher total mortality and higher mortality from nearly all causes, save COPD and suicide. But controlling for social characteristics — marital status, family size, income, and household crowding — virtually eliminates the racial gap in total mortality and reduces the racial gap for most causes, including circulatory diseases, cancer, respiratory diseases, accidents, infectious diseases, diabetes, and homicide (Centerwall 1984; Rogers 1992; Sterling, Rosenbaum & Weinkam 1993). We can expect similar results for other socially disadvantaged ethnic groups.

For example, the "epidemiological paradox" (Markides & Coreil 1986) — that Mexican and Caucasian Americans have similar life expectancies, even

though a greater proportion of Mexican Americans live in poverty and lack health insurance (Sorlie et al. 1993) — hides social differences in the causes of death. Compared to that of Caucasian Americans, Mexican American mortality is higher for accidents and three times as high for homicide (personal communication, Jeff Maurer, NCHS). The high rates of homicide for young Mexican Americans is due in part to gang violence (see Loya & Mercy 1985). The high accident rate among Mexican Americans is due to a variety of factors but may include lower socioeconomic status, which may result from driving older, poorly maintained cars and living in areas that require more driving time. Low incomes may also increase the risk of nonautomotive accidents because low incomes are associated with deteriorating housing and overcrowding (Shai, Rosenwaike & Rogers 1991).

Compared to Caucasians, Asians enjoy lower overall mortality and lower mortality from most causes of death. And compared to other subpopulations, including Caucasians, Asians have some of the highest income and educational levels. For instance, median family income in 1992 was $43,400 for Asians, $39,300 for Caucasians, $24,900 for Hispanic Americans, and $21,800 for African Americans (U.S. Bureau of the Census 1994). These relations suggest that the low mortality experienced by Asians is due in part to their favorable socioeconomic status and the benefits that ensue from it.

Compared to Caucasians, Native Americans are more than three times as likely to die from cirrhosis of the liver and more than two and one-half times as likely to die from accidents. On a Hopi reservation in northeastern Arizona, rollover crashes, pedestrian fatalities, and falls — from pickup trucks, mesas, and pueblo roofs — contribute to high accident mortality (Simpson et al. 1983). Native Americans may suffer more fatal accidents because they live in more dangerous environments or because, in general, lower socioeconomic status increases a person's risk of accidents. The high ratio for cirrhosis of the liver suggests that alcohol abuse may contribute to the high rate of accidents. Indeed, Native Americans are more than six times as likely to die from alcoholism as Caucasian Americans (HHS 1993). Rates of suicide and homicide are also high among Native Americans. In fact, Native Americans are 1.6 times as likely as Caucasian Americans to die from firearms (Fingerhut, Jones & Makuc 1994). High rates of suicide have been documented among the Hopi, Apache, Papago, Shoshone-Bannock, Northern Cheyenne, and Blackfeet. And even these high rates may understate reality, because Native American cultural and religious taboos against suicide may lead to an underreporting of it (Simpson et al. 1983).

Behavioral Health Characteristics Perspective

Cigarette smoking is considered the single most important preventable cause of death (CDC 1989). Thus, ethnic smoking patterns may translate into ethnic differences in mortality. Compared to other ethnic groups, including Caucasians, Asian and Pacific Islander Americans report "the lowest use of cigarettes, alcohol, marijuana, and cocaine and other hard drugs" (Zane & Kim 1994:318).

Compared to Caucasians, Mexican Americans generally smoke less and therefore have lower mortality from such smoking-related diseases as heart

disease, cancer, and COPD (see Castro, Baezconde-Garbanati & Beltran 1985). Indeed, the age-adjusted rates of death (per 100,000 population) from lung cancer in the U.S. in 1980 were 48 for Caucasians and 59 for African Americans, but only 29 for the Mexican born (Rosenwaike 1987). Thus, the healthy behavior of Mexican Americans may compensate in part for their social disadvantages.

Circulatory disease, respiratory disease, and cancer, all smoking-related causes of death, contribute disproportionately to the black/white gap in mortality. In fact, cancer, the second leading cause of death, contributes almost one-quarter of the black male excess in mortality (Rogers 1992). Several factors help explain these differences. For example, African American males are more likely to smoke than Caucasian males (Jaynes & Williams 1989; Manton, Patrick & Johnson 1987), though among smokers, African American males smoke fewer cigarettes than do Caucasian Americans (Kabat, Morabia & Wynder 1991).

This overview of ethnic differences in mortality suggests two main hypotheses. First, the social characteristics hypothesis suggests that controlling for social and economic characteristics will reduce the overall and cause-specific mortality gaps between Caucasians and other ethnic groups. These relations will emerge in two ways. Because Caucasians enjoy lower mortality and greater rates of marriage, more education, and higher incomes than Mexican, Native, and African Americans, controlling for social characteristics will narrow the mortality gap between Caucasians and these ethnic groups. And because Asians exhibit lower mortality and higher levels of income and education than Caucasians, controlling for socioeconomic status will reduce the mortality gap between these two groups. Second, the health characteristics hypothesis, which focuses on cigarette smoking, asserts that controlling for smoking will also narrow the overall and cause-specific mortality gap between Caucasian and Asian Americans, will have little effect on the gap between Caucasian and African Americans, and will widen the gap between Caucasian and Mexican and Native Americans. These relations will emerge because Caucasian and African Americans have high rates of cigarette smoking and because Caucasians are more likely than other groups to smoke large quantities of cigarettes.

Data and Methods

LINKED NATIONAL HEALTH INTERVIEW SURVEYS AND NATIONAL DEATH INDEX

The National Center for Health Statistics has now linked the National Health Interview Survey (NHIS) and the National Death Index (NDI) for the years 1986 through 1991 to create the NHIS-NDI file, a unique and powerful data base for mortality research (NCHS 1994c). The NHIS-NDI matched data set, which is nationally representative, provides annual cross-sectional data for the non-institutionalized U.S. civilian population, includes detailed covariates, and allows an examination of those who are exposed to the risk of death over time. The linked data sets alleviate the problem of inconsistencies in ethnic identification between two disparate data sources.

The NHIS-NDI data set, assembled for those individuals 18 years old and older, provides detailed data for NHIS subjects who have survived subsequent years and also for those who have died. NCHS devised a probabilistic matching

scheme that assigns weights to each of twelve items — social security number; first name; last name; middle initial; race; sex; marital status; day, month, and year of birth; state of birth; and state of residence — to determine the quality of potential matches (Horm 1993; NCHS 1994c). Patterson and Bilgrad (1986) have demonstrated that the matching methodology is highly accurate.

NHIS data are cross-sectional and derived from a household multistage sampling of the civilian noninstitutional population of the U.S. (NCHS 1980). The NHIS includes two types of questions: the Basic Health and Demographic Questionnaire (BHD), composed of "core" questions that are asked annually, and the Current Health Topic Questionnaires (CHT), called supplements, which focus on sets of health issues that vary from year to year (see Chyba & Washington 1993). The core questions include basic demographic items such as age, ethnicity, sex, marital status, income, and education. A wide variety of supplemental questions are asked on current health topics, including cigarette smoking; some of the supplemental questions are asked of the entire sample and others are asked of subsamples.

Our analyses use the NHIS 1987 Cancer Epidemiology (*N* = 22,080), the 1987 Cancer Control (*N* = 22,043), the 1988 Occupational Health (*N* = 44,233), and the 1990 Health Promotion and Disease Prevention Supplements (*N* = 41,104) (NCHS 1992, 1993a, 1993b, 1994c). We selected these supplements because they contain questions on demographic, social, economic, and behavioral health, specifically smoking behavior. We matched the NHIS records to the corresponding deaths in the NHIS-NDI file (NCHS 1994c) and excluded less than 5% of the sample that was other than Asian, Native, African, Mexican, or Caucasian American to create a final sample of 398,204 person-year records (394,071 survival records and 4,133 death records). This sample is based on individuals who survived from 1987 through 1991 or who died sometime within the period. Because interviews for each sample were conducted throughout the year (in either 1987, 1988, or 1990), respondents were exposed to the risk of death for half of the interview year and for the entire year for each subsequent year. Thus, individuals who were interviewed in 1987 and who survived through 1991 contributed 4½ person-years, while those who died contributed person-years up to the time of death. Similarly, those who were interviewed in 1988 or 1990 and who survived through 1991 contributed 3½ and 1½ person-years, respectively.

ETHNIC IDENTIFICATION

Historically, it has been difficult to calculate national mortality estimates or conduct comparative mortality analyses for various ethnic groups because researchers have used denominator information from a census or survey and numerator data from death registration, sources that ascertain ethnicity in different ways (see Hahn & Stroup 1994; Rosenwaike & Bradshaw 1988; Sullivan et al. 1984). Some individuals, especially those who have resided in the U.S. for long periods of time, who are in exogenous marriages, or who are of mixed ethnicities, may be reported of one ethnicity in a census or survey and of another on death records (see Barringer, Gardner & Levin 1993). When inconsistencies arise, it is usually because individuals who were coded as

Mexican, Native, or Asian American in a census or survey were coded Caucasian at death (Sorlie, Rogot & Johnson 1992). This is especially apparent for Native Americans in California, Oklahoma, Oregon, and Washington (HHS 1993). These inconsistent codes can artificially lower life expectancy estimates for Caucasians and artificially raise them for other ethnic subpopulations. It seems desirable, therefore, that researchers make greater use of linked files, like the matched NHIS-NDI data set, where ethnic information is consistent for survivors and decedents. NCHS provides ethnicity on the NHIS-NDI file from the responses to the NHIS.

Because of the unique structure of this data set, we present some of the first national mortality comparisons of Native Americans to other ethnic groups. Mortality figures for Native Americans are infrequent; those figures that are presented are often for the Indian Health Service (IHS) areas, which include only the thirty-three states for which IHS is responsible (HHS 1993). These numbers are subject to substantial biases because of the different data sources for numerator and denominator data and different ways to ascertain ethnic identification. Thus, the Native American comparisons presented in this article are some of the very few national comparisons extant based on consistent ethnic codes for the numerator and denominator.

The NHIS asks whether the person falls into any of the following groups: Aleut, Eskimo, or American Indian; Asian or Pacific Islander; black; white; or other. A follow-up question asks whether the person or the person's ancestors is (are) Puerto Rican, Cuban, Mexican/Mexicano, Mexican American, Chicano, Other Latin American, or Other Spanish (Chyba & Washington 1993). In this study, we focus on the largest Hispanic subpopulation, Mexican Americans (Mexican/Mexicano, Mexican American, and Chicano). We exclude small groups of Cubans, Puerto Ricans, and other Hispanics because of insufficient numbers of deaths. To provide exclusive categories, we define our other categories as non-Hispanic Native Americans (Aleut, Eskimo, or American Indians), African Americans (blacks), Caucasian Americans (non-Hispanic whites), and Asian Americans (Asian or Pacific Islander). Although the Asian population is a diverse group in terms of country of origin, language, and customs, we examine the group in its entirety because NCHS does not differentiate Asian subpopulations and because there were few Asian deaths overall.[1] We follow convention by comparing the mortality of Mexican, Asian, Native, and African Americans to that of Caucasian Americans. The referent could, however, be any other ethnic group or, say, the average total U.S. population. The NHIS oversamples some ethnic groups, including Hispanics, to enable more accurate estimations.

Besides ethnicity, our independent variables are age, sex, education, income, marital status, and smoking status. Age is divided into five-year age categories except for the two extreme categories: under 20 (that is, ages 18 and 19), and ages 85 and above. We employed the linear relation of age because previous studies have demonstrated that age transformations of the five-year categories into age-logged or age-squared terms do not statistically improve the model fit (see, for examples, Elo & Preston 1994; Rogers 1992). We used four categories for education: eighth grade or less, ninth grade to eleventh grade, high school graduation (the referent), and some college (that is, thirteen years of education

or more). We include a broad measure of family income, measured as less than $20,000 or $20,000 or more for the following reasons. First, Williams and Collins (1995) report that "health gains due to income are small for households above $20,000 per year" (353). Second, the nonresponse rate is less than 2%, compared to a more detailed income measure, in which the nonresponse rate is 13%. Thus, we adopt the income measure with the highest response rate and that captures the major variations within health and mortality.[2] Marital status is coded as married (the referent), previously married, or never married. Smoking status is coded as never (the referent), former light (used to smoke less than a pack of cigarettes per day), former moderate-to-heavy (used to smoke a pack or more of cigarettes per day), current light (less than a pack of cigarettes per day), or current moderate-to-heavy (a pack or more of cigarettes per day). In those few instances that the marital status, income, education, or smoking values were missing, we stratified the sample by age, sex, and ethnicity, and imputed new values.

STATISTICAL ANALYSES

To examine ethnicity and mortality within a multivariate framework, we use discrete-time event history methods for categorical dependent variables (Allison 1982, 1984). The discrete-time hazard model, which is based on pooled intervals, deals with censored observations (deaths) and provides consistent estimators of the true standard errors (Teachman, Tedrow & Hill 1994). We recognize, of course, that the discrete-time model approximates hazard rates. The approximation is extremely good if the hazard of dying is relatively low (which it is until the highest ages). Moreover, even if the approximation is not extremely good, the values of the predictor variables will be similar. We report the coefficients in the form of odds ratios (see Hosmer & Lemeshow 1989). Because NHIS includes a complex clustering and stratification sampling design, we calculate hazard results for overall mortality with SUDAAN, a computer program that differentially weights sample strata to correctly estimate variances (Shah et al. 1990). For the cause-of-death analysis, we follow Allison's (1982) advice and use SUDAAN to calculate a series of equations, each of which compares individuals who die from a particular cause to those who survive the period. Because NHIS oversamples African Americans and Mexican Americans (see Massey et al. 1989), correctly incorporating the sample design generally produces larger standard errors and therefore more conservative statistical tests between ethnic groups.

We use five causes of death: four categories based on the three-digit codes presented in the *International Classification of Diseases* (HHS 1990) and a residual category. The four specific groupings are circulatory disease (390-459), cancer (ICD 140-239), respiratory disease (ICD 466-496), and social pathologies, which include suicide, accidents, homicide, and cirrhosis of the liver (ICD 571 and ICD E800-E999). This scheme is similar to those used in previous studies (i.e., Nam, Hummer & Rogers 1994; Potter 1991; Rogers 1992), although the categories are condensed because of cell sizes.

Results

Table 1 describes, by ethnicity, the demographic, familial, socioeconomic, and smoking status of those who were alive and those who died during the period from 1987 through 1991. For each ethnic group, individuals are generally more likely to die if they are older, male, previously married, less educated, or poorer, or if they smoked. Among survivors, there are variations in the distribution of these social and health characteristics by ethnic group. African Americans are the least likely to be married; a little over one-third of all African Americans are married. Asian Americans are by far the most educated ethnic group; more than 60% of Asians are college graduates. Asian and Caucasian Americans realize the greatest incomes; about 60% of each group earn over $20,000. Mexican Americans and Asian Americans tend not to smoke cigarettes; about 60% of Mexican Americans and more than 70% of Asians have never smoked cigarettes. Caucasians, on the other hand, have high rates of smoking, and especially high rates of quitting at high consumption levels. In fact, more than 15% of Caucasians are former heavy smokers, a status shown to be a high risk for several causes of mortality (Nam, Hummer & Rogers 1994).

Table 1 also reveals ethnic differences in causes of death. A high proportion of Asian Americans die from chronic degenerative diseases; circulatory diseases and cancer account for more than 80% of all Asian deaths. A substantial percentage of Caucasians die from these same causes, but many also die from respiratory diseases. Mexican, Native, and African Americans display high percentages of mortality from social pathologies. Indeed, more than one-quarter of all Native American deaths are attributed to cirrhosis of the liver and to accidents and other violent causes of death.

Table 1 includes sample sizes and shows some heterogeneity between ethnic groups and socioeconomic and behavioral factors. Of 398,204 total person-years, Caucasian Americans are the largest group, followed in turn by African, Mexican, Asian, and Native Americans. These distributions are affected, of course, by the focus on ages 18 and above and by the exclusion of other, smaller ethnic groups. Even so, Native Americans, while contributing almost 2,500 person-years, still represent a small subpopulation. Thus, because of relatively small sample sizes, estimates of Native and Asian American mortality should be interpreted cautiously. Some groups illustrate more homogeneity than others. For example, 85% of all Asian Americans have attained at least a high school diploma. Mexican Americans display much more educational variation: 50% have attained 12 years of schooling, but 30% have fewer than 9 years of education.

Table 1, while informative, does not simultaneously control for multiple factors. For such analyses, we turn to Table 2, which shows ethnic differences in mortality, controlling for various factors. By sequentially adding controls, we can determine the influence of each variable on the relationship between ethnicity and mortality. For example, a comparison of models 1 and 2 shows the effect of marital status on that relation. Comparing models 1 and 3 or models 1 and 4 shows the effect of socioeconomic status. Comparing models 1 and 6 shows how much smoking affects ethnic differences in mortality. Model 7 illustrates how all variables together affect ethnic mortality.

Model 1 incorporates a conventional demographic approach to ethnic differences in mortality by controlling for age and sex. It shows that, compared to Caucasian Americans, African, Mexican, and Native Americans have higher mortality and Asian Americans exhibit lower mortality. Compared to Caucasian Americans, African Americans are about 50% more likely to die, whereas Asians are almost half as likely to die. The mortality of Mexican and Native Americans is similar to the mortality of Caucasian Americans. The subsequent models show whether these general patterns change with the introduction of other social, economic, or behavioral health factors.

Model 2, which controls for marital status, does not substantially alter ethnic mortality patterns. But models 3, 4, and 5, which control for socioeconomic differences, show that socioeconomic status substantially affects the mortality gap between Caucasian and Mexican, Native, and African Americans. For instance, controlling for age and sex reveals a 48% gap between African and Caucasian Americans, but simultaneously controlling for education reduces the gap to a 32% difference. Compared to Caucasian Americans, Mexican Americans exhibit the same odds of death when age and sex are controlled, but lower odds when education is also controlled. Thus, a major contributor to ethnic differences in mortality is socioeconomic status. The fact that Mexican, Native, and African Americans acquire less education and income than Caucasian Americans contributes to their mortality.

Controlling for smoking status, in model 6, substantially affects ethnic differences in overall mortality for Mexican, Asian, and Caucasian Americans. Mexican and Caucasian Americans exhibit the same risk of dying in model 1, but once smoking is controlled, Mexican Americans exhibit a higher risk of death. Thus, once the risky smoking behavior of Caucasians is taken into account, the mortality gap between them and Mexican Americans widens. Through similar logic, the statistically significant differences between Asian and Caucasian mortality in model 1 disappears with controls for smoking. Thus, the high rate of smoking among Caucasian Americans hampers their ability to mirror the low Asian mortality and the low smoking prevalence rates among Mexican Americans helps compensate for their lower socioeconomic status and provides them with mortality rates comparable to their Caucasian counterparts.

Model 7 simultaneously controls for demographic, social, and behavioral health characteristics. With such controls, there is no significant mortality difference between Caucasian and Mexican Americans or between Caucasian and Native Americans, the gap narrows substantially between Caucasian and African Americans and also narrows between Caucasian and Asian Americans. Other referents than Caucasians would of course yield different odds ratios. For instance, model 7 (including all variables) shows that African Americans are 28% more likely to die than Caucasian Americans; but over twice as likely to die as Asians $\left(e^{(\ln(1.28)-\ln(.62))}\right)$. This table underscores the impact of familial, socioeconomic, and behavioral health variables on ethnic differences in overall mortality. To understand which causes of death contribute to these mortality differences, we turn to Table 3.

Table 3 shows cause-specific ethnic differences in mortality, controlling for demographic, social, and economic factors and for smoking. Compared to Caucasian Americans, African Americans demonstrate slightly higher mortality from cancer and circulatory diseases and significantly higher mortality from social pathologies and residual causes; Mexican and Native Americans also have higher mortality rates from social pathologies. In fact, Native Americans have over 2.7 times the Caucasian American mortality rate in this category, which is dominated by automobile accidents. Asian Americans have low mortality from all causes when compared to Caucasian Americans. To determine which factors are most responsible for these ethnic patterns in mortality, we turn to Table 4.

Table 4 presents four separate models for cause-specific mortality: one controlling for demographic variables only, one controlling for demographic and

social factors, another controlling for demographic factors and smoking, and last, a replication of the full model used in Table 3. Compared to Caucasian American mortality, Mexican, Native, and African American mortality is reduced with controls for socioeconomic status. Such reductions are small for cancer and circulatory diseases, where the mortality gap between Caucasians and other groups is already small, but are larger for social pathologies. For example, compared to Caucasian Americans of the same age and sex, Native Americans are 3.6 times as likely to die from social pathologies but only 2.9 times as likely to die if we control for social factors. Similar results are obtained for Mexican and African Americans. Thus, the high mortality rate from social pathologies among Mexican, Native, and African Americans is due in large part to social characteristics — differences in marital status, education, and income.

Compared to Caucasian Americans of the same age and sex, African Americans are 35% more likely to die from circulatory diseases. But when socioeconomic status and marital status are controlled, the gap closes significantly, to a 14% difference. The gap between Caucasian and African Americans witnesses similar narrowing once socioeconomic status is controlled for all other causes of death.

Compared to Caucasian Americans of the same age and sex, Mexican Americans experience the same or lower mortality for circulatory diseases, cancer, respiratory diseases, and residual causes of death. Once socioeconomic status and marital status are controlled, Mexican American mortality drops further for all these causes of death. But when cigarette smoking is controlled, Mexican American mortality increases — for cancer, by 14%. Similar relations exist for African Americans: whereas African Americans are just 15% more likely than Caucasian Americans to die from cancer in the demographic model, they are almost 25% more likely to die when cigarette smoking is controlled. Because Caucasian Americans exhibit heavy rates of cigarette consumption, followed by African Americans and then by Mexican Americans, controlling for smoking widens the mortality gap for Caucasian and African Americans and for Caucasian and Mexican Americans for smoking-related causes of death.

On the other hand, controlling for cigarette smoking generally narrows the cause-specific mortality gaps between Asian and Caucasian Americans. Because Caucasians smoke more than Asian Americans, and because Asians enjoy lower mortality in general, controlling for smoking reduces the gap between these two groups for residual causes of death and for the two causes of death directly affected by smoking: circulatory diseases and cancer. Asians are 42% less likely than Caucasians to die from cancer when age and sex are controlled, but only 23% less likely than Caucasians to die when cigarette smoking is controlled.

Conclusions

This study has provided new, detailed, and comparative mortality results by ethnicity. Past studies have often compared only one or two ethnic groups, have used disparate categorization between numerator and denominator data, and have not controlled for other covariates. Therefore, our results offer more

detailed, definitive results by ethnic groups on a national level and provide controls for covariates.

This study underscores the importance of examining ethnic differences from social and behavioral health as well as demographic perspectives. For example, from a social characteristics perspective, we find that the high mortality from accidents and violence for Mexican, Native, and African Americans is due in large part to higher rates of poverty, lower levels of education, and marital disruption — that is, to their social disadvantages. The behavioral health characteristics perspective helps to explain the epidemiologic paradox, or why Mexican and Caucasian Americans experience similar mortality rates, even though a greater proportion of Mexican Americans live in poverty and lack health insurance (Markides & Coreil 1986; Sorlie et al. 1993). Our findings suggest that the healthy behavior of Mexican Americans (their tendency not to smoke) compensates in part for their social disadvantages. In contrast, Caucasians as a group compromise their low mortality through heavy, prolonged smoking.

We followed convention by using Caucasians as the referent group. An alternate approach would be to use Asians, the group with the lowest mortality. The tables provide the information needed for such comparisons, which would increase the odds ratio for many ethnic groups; as we have already demonstrated from Table 2, African Americans would move from an overall mortality excess of 28% (compared to Caucasians) to an excess greater than twofold (compared to Asians).

The demographic, social characteristic, and behavioral perspectives each aid in the explanation of ethnic differences in mortality. For instance, the sources of mortality differences are more clearly understood when demographic characteristics are taken into account. However, it is evident from this and other research that ethnic mortality differences exist beyond the demographic composition of the respective populations.

This article also demonstrates that the social characteristic hypothesis is important in explaining ethnic mortality differences. Asian Americans clearly have the lowest mortality and most advantaged socioeconomic composition of the groups studied; when socioeconomic characteristics are controlled, their mortality advantage relative to the other groups decreases. Similarly, the least socioeconomically advantaged groups — Mexican, Native, and African Americans — are able to reduce their mortality gaps with Caucasian and Asian Americans when social characteristics are controlled. Thus, improvements in further reducing socioeconomic gaps between U.S. ethnic groups may also have an impact in reducing mortality differences between these groups. Furthermore, the impact of the social characteristic explanation may even be stronger if additional measures of social inequality — such as wealth, occupational prestige, and discrimination — were measured and taken into account (Hummer 1996).

In addition to the demographic and social characteristic perspectives, this article demonstrates that the behavioral health perspective helps in understanding ethnic mortality differences. However, controlling for such factors — in this case smoking — may also work to statistically widen mortality differences. Here, it is clear that the mortality advantage of Caucasian Americans relative to

African, Mexican, and Native Americans would be even greater if cigarette smoking were eliminated. It would be interesting to speculate whether similar effects would be observed if other health behaviors, such as diet or the use of alcohol or drugs, were examined.

The NHIS-NDI linked data set enables researchers to better examine ethnic mortality patterns. Future research could explore multiple-cause mortality, which considers all the identifiable medical causes entered on the death certificate (see Nam 1990). Combinations of causes can be more lethal than single causes, can affect the timing of death, and can influence the mortality differences between subpopulations.

It is also important to examine mortality differences within ethnic subpopulations. Some groups used here have subgroups that vary substantially by history, geography, language, and custom; consider the differences among Apaches, Navahos, and Sioux or among Chinese, Japanese, and Laotians. Researchers could begin examining different African American subpopulations, especially as larger numbers of individuals immigrate to the U.S. from Africa, the West Indies, South and Central America, and Europe (Bryce-Laporte 1993). And although Caucasian Americans have conventionally been treated as a homogeneous group, there are differences by country of origin, language spoken, religion, and time since migration that may influence mortality (Rosenwaike & Hempstead 1990).

Mortality is a driving force behind the size and composition of ethnic populations, which in turn affect natural increase, age structure, cohort effects, and family formation and composition. Therefore, information on the current and future mortality of ethnic groups is crucial to understanding the dynamics of our society. And these results give us added insight into the demographic, social, and health mechanisms that allow us to persevere or to perish.

Notes

1. The U.S. Bureau of the Census is primarily responsible for the design and collection of NHIS data. The NHIS sample includes about 10% of the approximately 1,900 primary sampling units (PSUs) that cover the U.S. "A PSU consists of a county, a small group of contiguous counties, or a metropolitan statistical area" (Massey et al. 1989:2). Although NHIS data represent the entire U.S. population, sampling by geographic areas means that larger subgroups within the Asian and Native American populations are more likely to represent the entire ethnic population. For example, mortality rates for Native Americans may reflect more the Cherokee and Navaho experiences, the two largest Indian subpopulations, than, say, those of the Acoma or Taos Indians. Similarly, mortality rates for Asians may reflect more the Chinese experience, the largest U.S. Asian subpopulation, than, say, that of the Hmong (U.S. Bureau of the Census 1994). If the mortality experiences of the Hmong and Chinese are similar, then no biases are introduced. If the Hmong have much higher mortality than the Chinese, then our Asian estimates will be artificially low. But such bias will be slight because even high mortality contributed by a proportionately small group will negligibly affect the overall ethnic group's mortality.

2. Different approaches toward capturing income differences may yield slightly different results and interpretations. For other income adjustments, refer to Buhmann et al. (1988) for income equivalence scales, or Ruggles (1990) for poverty indexes. Although we assert that mortality is reflected more directly and accurately by an income measure that is answered by the greatest proportion of respondents, that is clearly constructed, and that is not contaminated by other variables, we leave this issue to the reader to weigh and for future research to resolve.

Book Reviews

Mental Disorder and Crime.
Edited by Sheilagh Hodgins. Sage Publications. 1993, 339 pp. Cloth, $55.00; paper, $26.00.

Reviewer: WALTER R. GOVE, *Vanderbilt University*

According to Sheilagh Hodgins people frequently fear that the mentally ill are likely to be violent, but members of the scientific community have not been convinced this is the case. However, she holds that "in recent years much evidence has suggested that major mental disorders (schizophrenic, major affective disorders, and other psychiatric disorders) and violence are associated," and this provides the premise around which this book is framed. The book is divided into three parts. Part 1, "The Criminology of Mentally Disordered Persons," is comprised of six papers that are largely concerned with developing a descriptive understanding of the association between mental disorders, crime, and violent behavior. Part 2, "Risk Factors for Violent Behavior," contains eight papers, most of which are concerned with developing an understanding of the causes of violence. The concluding part of the book has three papers that provide a rough assessment of the evidence linking mental disorders and crime and discusses implications for intervention.

This book is an attempt to present an overview of recent evidence on the relationship between mental disorders and crime and to indicate what is unknown but needs to be known. As a consequence of this latter concern, a few of the papers are primarily a description of, and justification for, major research programs presently in process. To fully understand and evaluate the papers dealing with the relationship between mental disorders and crime the reader needs a working knowledge of the Diagnostic and Statistical Manual (DSM III, DSMIIIR, or DSMIV) and how the mental disorders described in this manual are measured in community studies (e.g., the Diagnostic Interview schedule [DIS] used in the Epidemiologic Attachment Area [ECA] study). This is particularly important as the term *mental disorder* is used differently by the various authors; fortunately, how it is being used is clearly stated at the beginning of each chapter. To fully understand and evaluate many of the papers in part 2 the reader will need an understanding of basic knowledge in neuroscience and behavioral endocrinology.

This book is aimed at a professional audience and all the chapters have something to recommend them. I personally learned the most from the following chapters: (1) Sheilagh Hodgins on "The Criminality of Mentally Disordered Persons," which includes detailed data on how the comorbidity of mental disorders is related to crime in the Swedish Metropolitan Project; (2) Lee Robins, who makes a similar, but much more elaborate presentation using the ECA data;

(3) Pamela Taylor who shows how the violent criminal behavior of persons who have an acute psychotic disorder differs from most violent criminal behavior; (4) Matti Virkkunen and Merku Linnoila, who indicate the ways in which the neurophysiology of the brain, particularly low levels of serotonin, are related to violent behavior; (5) Robert 0. Pihl and Jordan Peterson, who describe the relationship between alcohol and aggressive behavior and focus on how alcohol may *increase* pain sensitivity while simultaneously reducing both the fear associated with potential threats and a person's response flexibility; and (6) John Monchan, who gives a good overview of the evidence between mental disorders and violence.

Taken as a whole I think the material in this book lends itself to a number of conclusions that can be reached with a reasonably high level of certainty: (1) Persons who abuse alcohol and/or drugs have very high rates of criminal behavior (chapters 1, 9, and 15). (2) Persons with a psychopathological (or antisocial or sociopathic) personality have very high rates of criminal behavior (chapters 6, 7, 9, 11, 12, and 15). Furthermore, the relationship between psychopathic traits is not substantively affected by controls for serious mental disorders such as psychosis (chapter 6). (3) Persons with major disorders of thought or affect (e.g. psychoses, schizophrenia, affective psychoses, paranoid states) have relatively high levels of criminality (chapters 1, 9, and 15). However, when substance abuse (chapter 1) or substance abuse and an antisocial behavior (chapter 9) are controlled for, the relationship between the major mental disorders and the high rate of criminality becomes statistically nonsignificant. (4) Most violent psychotic offenders differ from other violent offenders in that their violent behavior appears to be a direct response to psychotic symptoms, particularly delusions and hallucinations (chapter 4, also see chapters 3 and 15). (5) Disruptive parenting practices result in antisocial behavior in children and are a precursor of aggressive offending in personality disordered adults (chapters 7 and 8). (6) Understanding why the variation among persons in impulsivity, hyperactivity, and sensation seeking are linked to habitual violent behavior requires an understanding of basic neuroanatomy, and the ways in which monoamine oxidase activity, serotonin, and other neurotransmitters affect the functioning of the brain (chapters 10, 11, and 12). As the work of sociologists increasingly indicates that impulsivity and sensation seeking is related to criminal activity, sociologists need to be taking this literature into account.

This is an important book. However, I am bothered by the fact that no one raises the possibility that the criminal behavior of persons with personality disorders and persons who abuse alcohol and/or drugs might be best viewed as volitional acts of deviant behavior. As this issue is not addressed, the book is indicative of a trend to medicalize deviant behavior without a consideration of all the issues involved.

Cultivating Differences: Symbolic Boundaries and the Making of Inequality. *Edited by Michèle Lamont and Marcel Fournier.* University of Chicago Press, 1992. 346 pp. Cloth, $49.95; paper, $20.00.

Reviewer: ANNE BOWLER, *University of Delaware*

This excellent volume is required reading for sociologists working in the area of culture and the arts. It also should be of interest to sociologists seeking a clearer understanding of the role of culture in "the making of inequality." *Cultivating Differences* is distinguished by the quality of its individual contributions, whose authors bring a sophisticated approach to the subject of culture, including Herbert Gans in his wonderful preface. This does not mean that readers should expect to find a single theoretical orientation or model. Rather, each contributor rejects the generally reductive conclusion that culture can be read as a simple reflection of social structure and instead recognizes and seeks to explicate the complexity of the culture-society relationship.

Part 1 explores the institutionalization of cultural categories in modern society. Paul DiMaggio maps the establishment of a "high cultural model" in American drama, opera, and dance in the first four decades of this century. Diana Crane challenges the conceptual adequacy of the categories of high and popular culture in contemporary society. Arguing that "it is more meaningful to categorize recorded cultures in terms of the environments in which they are created, produced, and disseminated," she offers insight into conditions under which institutional arrangements shape systems of classification. Joseph Gusfield analyzes the discourse of purity and the body in the history of the natural foods movement. Nicola Beisel examines the moral crusade led by American reform leader Anthony Comstock, who mobilized the social categories of youth, class, and ethnicity to redefine boundaries between obscenity and literature in the late nineteenth century.

Part 3 reexamines a theme of earlier work in the sociology of culture: the role of high culture as a tool for creating and reinforcing inequalities. David Halle challenges the validity of this function in his study of consumers of abstract art, reporting on buyers who eschew claims to the superior intellectual capacities required to admire abstract art in favor of the decorative qualities of works. In contrast, essays by Richard Peterson and Albert Simkus on musical taste and Vera Zolberg on the museum indicate that high culture continues to be an important signifier of status, albeit in increasingly more complex and variegated ways. Peterson and Simkus examine the relationship between musical taste and occupational status. While they find a hierarchy of cultural preferences by class, it is "pyramidal" in structure, with less consensus on ranking as one moves down the social scale. In a comparative analysis of French and American art museums, Zolberg explains why the democratic goals of museum administrators often remain unfulfilled.

Part 3 demonstrates the significance of gender and ethnicity as bases of distinction and stratification. Randall Collins maps the intersection of class and gender in the "status-producing" activities performed by women in the workplace and at home. Cynthia Fuchs Epstein elucidates the cultural bases and dynamics of gender boundaries in the workplace. In an essay directed in part toward a

retheorization of Bourdieu's model of cultural capital, John Hall argues that neither gender nor ethnicity can be viewed as "secondary" to class.

Finally, part 4 raises the question of exclusion and the polity. Jeffrey Alexander examines the symbolic dimension of civil society. He presents a critical exegesis of the binary character of "civil discourse" as it operates at three levels (motives, relations, institutions), dividing society into "those who deserve inclusion and those who do not." Alan Wolfe, in turn, locates a tension between the very terms *inclusion* and *exclusion* in a liberal democratic society. The history of modern democracy is one of inclusion and yet a totally inclusive society, Wolfe argues, is neither possible nor desirable. The key for Wolfe is that not all boundaries are hierarchical and oppressive nor do all distinctions involve a process of "othering." The task then becomes one that combines a democratic commitment to universal rights with respect for specific differences.

The Dream of a New Social Order: Popular Magazines in America, 1893-1914.
By Matthew Schneirov. Columbia University Press, 1994. 357 pp. $29.50.

Reviewer: KAREN A. CERULO, *Rutgers University*

Matthew Schneirov's *The Dream of a New Social Order* provides a fascinating window on one of the most pivotal periods in U.S. history, the decades that bridged the nineteenth and twentieth century. For many that window may seemingly emanate from an unexpected source, for it is through the pages of popular magazines that Schneirov provides this slice of social history.

Schneirov guides his readers through the transition from homogeneous to heterogeneous America. In 1893 the U.S. was still dominated by middle- and upper-class Protestant ideals, but by 1914 the nation was grappling with an extended set of beliefs and practices — values and norms generated by new social phenomena such as the growth of cities, diverse immigration, industrial expansion, and sheer social energy. Popular magazines both reflected and, according to Schneirov, provoked the changing tenor of the times. Indeed, Schneirov convincingly demonstrates the ways in which magazine editors of the period intentionally blurred the boundaries and categories of postbellum America in an effective effort to construct a unique blueprint for the future of U.S. culture. Via this blueprint, magazines helped ease the nation's passage to an industrially based society.

Although the current role of magazines in the U.S. might tempt readers to question Schneirov's attention to the medium, the author effectively allays any such doubts. Early on he documents the growth of the Progressive Era's magazine industry (circulation tripled between 1890 and 1905) and the scope of the medium's reach — "65 million or about three magazines for every four people." Indeed, during this period magazines could be considered *the* mass media of the nation. They were an affordable, readable, and widely dispersed source of information and commentary.

What sort of blueprint were magazine editors projecting to their readers? Schneirov argues that dreams of abundance, social control, and social justice comprised the agenda of these editors — three dreams fueled by turn-of-the-century technology's redefinition of activity, motion, and energy as well as by the

changing stance of America's middle class. In essence, America's changing social structure provided a context for magazine editors as they instilled public desire for their own special visions of power and pleasure.

Schneirov's data are impressive. His conclusions stem from an exhaustive analysis of every issue of *Cosmopolitan* magazine published between 1893 and 1914. Schneirov also includes a healthy dose of articles from *McClure's* and *Munsey's* and a more select sample of stories from publications such as the *Atlantic Monthly, Century, Harper's Monthly, Scribner's,* and *Women's Home Companion*. The coverage is broad, giving readers a rich snapshot of the popular philosophies of the era.

In addition to its value as social history, *The Dream of a New Social Order* should be of great interest to sociologists of culture. Its theoretical base is true to Griswold's notions of a "cultural diamond." Schneirov considers the intentionality driving magazine editors (i.e., the cultural producers) and examines the impact of editorial decisions on both the medium's audience and the cultural object itself. Finally, he explores such issues within the special context of the historical times. Schneirov thus provides a valuable application of an inclusive cultural model. Those teaching general seminars in culture may find his book a useful case study illustrating Griswold's theoretical approach. Further, the volume's readability and topic make it suitable for advanced undergraduate or graduate courses in American studies, media history, modernization, and social change.

Politics and Religion in Central and Eastern Europe: Traditions and Transitions. *Edited by William H. Swatos Jr.* Praeger, 1994. 230 pp. $59.95.

Reviewer: MICHELE DILLON, *Yale University*

The essays in this volume provide a useful introduction to the varying ways in which historically embedded interconnections between religion and national identity in several Central and East European countries contributed to and shaped the collapse of Soviet Communism in 1989. Especially welcome is the inclusion in its purview of countries that have received little analytical attention from sociologists and political scientists. Thus, for example, the reader is alerted to the cultural and political importance of religion — whether as oppositional discourse, institutional space for "civil society," or theological belief system — not only in Poland (which is discussed extensively both in this work and in the broader literature) but also in Lithuania, Estonia, Latvia, Ukraine, Georgia, Armenia, Byelorussia, Russia, Hungary, East Germany, Slovakia, the Czech Republic, and the former Yugoslavia.

Irrespective of the different theoretical frameworks employed by the contributors, many of the essays highlight the legitimation problems and resulting practical implications arising from the inevitable interpenetration and mutual adaptation of religious and political institutions. Patrick Michel, in particular, emphasizes what he sees as the "impossibility" of drawing a boundary between the political and religious domains under Soviet Communism. Focusing on Poland, Michel argues that the contradictions inherent in the Soviet system meant that the religious field was doubly solicited by the political regime as a potential instrument of legitimation and by the people as a source of transformation: "the

religious found itself both restrained from entering on an equal footing a field that was not its own and working simultaneously on the consolidation of the regime (the price of institutional survival) and on its destruction, as a vector of disalienation, detotalization, and desovietization (the price of safeguarding its identity)."

As Hank Johnston notes, however, the relationship between the state and the national church varies, depending on historical, geopolitical, and security factors; regime ideology; and control of the local population. He emphasizes that there is no linear relationship between the freedom given to the national church and its affinity with nationalist causes. Church collaboration or complicity with the regime thus has different implications in different cultural contexts — in Armenia, for example, Johnston observes that the church's complicity with the regime did not damage its legitimacy among the population. On the other hand, Natalia Dinello's analysis of Russian public opinion data suggests that "the only institution that inspired considerable trust on the eve of the breakdown of the Soviet Union was the Russian Orthodox Church," a finding she attributes to the fact that "the church was neither involved in the establishment of the Soviet regime nor held responsible for the failures of perestroika."

Similarly, the impact of the collapse of Soviet Communism on religious revitalization varies across different societal contexts, a point stressed by several of the contributors (see especially the chapters by Irena Borowik, Luigi Tomasi, and Ivan Varga). A complicating factor shaping the cultural strength of religious institutions in the postcommunist era is their organizational adaptability to broader intrainstitutional dynamics. Thus Catholic churches in eastern Europe must now confront the challenge of cultural openness articulated 30 years ago by Vatican II (see Varga), while reunited Evangelical German churches must adjust administratively to one another (see Beckley, Chalfant, and Johnson); furthermore, both the Evangelical German Church and the Slovak Evangelical Church (see Gluchman) must carve out a new, morally authoritative identity.

Finally, although religion may well have lost some of its power to enchant, all the essays in this volume serve as reminders that religion continues to provide institutions and social movements with a rich resource and an anchor for culturally contested symbols and meanings. This function is perhaps expressed most concretely by the Bosnian-Croat conflict over "ownership" of Medjugorje, the site of a populist Catholic shrine located in Bosnia-Hercegovina (see Markle and McCrea). This book is a valuable contribution not just to students interested in eastern Europe or religion but to anyone seeking a deeper understanding of the multifaceted ways in which culture both drives and constrains social and political action.

Chinese Families in the Post-Mao Era.
Edited by Deborah Davis and Stevan Harrell. University of California Press, 1993. 370 pp. Cloth, $55.00; paper, $17.00.

Reviewer: YU XIE, *University of Michigan*

This valuable volume includes contributions from five sociologists, five anthropologists, and a psychiatrist. Pooling fresh empirical results from ten independent research projects conducted in different locales in China, the book provides the

latest evidence on recent changes in the contemporary Chinese family and their implications. Written for a broad audience, both China specialists and social scientists with an interest in the family will find it valuable.

Although the essays in this book were first presented at a conference, they are not part of a single, organized research effort. Methods, data sources, and field locations vary greatly. However, Deborah Davis and Stevan Harrell have done a fine job of keeping a coherent focus throughout the volume. Specifically, the book addresses the following question: What are the consequences for the family of the rapid political, social, and demographic changes in China that began in 1978 and continue today in full force? In their introductory essay, Davis and Harrell provide a good historical background and set up a broad conceptual framework for later chapters that recognizes cultural, demographic, economic, and political forces at work and their interplays in affecting processes related to such family outcomes as marriage, childbearing, and caring for dependents.

A review chapter by Jonathan Unger on urban families is followed by ten remaining chapters that are all based on original research on a variety of topics in different settings. There are three chapters on household structure, by Davis (in Shanghai), Harrell (in rural Sichuan), and Graham E. Johnson (in rural Guangdong); three on marriage, by Mark Selden (in rural Hebei), Helen F. Siu (in rural Guangdong), and Martin King Whyte (in Chengdu); two on childbearing, by Susan Greenhalgh (in rural Shaanxi) and Hill Gates (in Taibei and Chengdu); one on caring for family members with schizophrenia, by Michael R. Phillips (in various cities); and one on caring for the elderly, by Charlotte Ikels (in Guangzhou).

In general, the empirical work is well executed and the associated interpretations well thought out. The only problematic essay is the one by Gates on birth limitation among urban capital-owning women. Her thesis is basically Marxian; she argues that among petty-capitalist women the power derived from owning capital positions them to determine their own destiny by limiting their fertility. Her evidence, however, is weak and inconclusive. The data she uses from her interviews with small groups of women do not rule out alternative explanations. For example, economists have long argued that a higher earning capacity increases women's opportunity cost for childbearing; furthermore, the modernization perspective predicts that better-educated women tend to be more in control of their childbearing decisions and that they have lower fertility rates. That is to say, the lower fertility levels that Gates observed among capital-owning women may have had nothing to do with their ownership of the means of production. Gates's tendency to twist evidence to fit her argument is apparent in her statement that "life expectancies for Chinese women were lower than those for men," for which she provides no historical context, leading readers to believe that her remark applies to the post-Mao period. I consulted her source and found that since the 1960s life expectancies for Chinese women have been consistently higher than those for men.

All of the authors base their research on relatively small samples (between 100 and 1,000 cases) that each drew from local communities, which is somewhat surprising as well as puzzling. Why not have made use of existing large-scale national data sources? For example, high-quality unit-record data from the 1982 Chinese census have been available for some time and could have been used by the authors. A few large fertility surveys are also available. While there might be

a subdisciplinary culture opposed to the use of secondary data among China specialists, I see no justification for such opposition. From a statistical point of view, more information should be no worse than less information. In the long run, it is important that China specialists begin to share data and become accustomed to secondary data analyses if they wish to make cumulative progress.

Voicing Social Concern.
By Otto N. Larsen. University Press of America, 1994. 306 pp. $32.50.

Reviewer: KAREN A. CERULO, *Rutgers University*

The traditional publication forum for sociologists holds little opportunity for the placement of essays and commentaries. The professional journals are almost solely restricted to complex theoretical treatises or systematic empirical research. Few homes are provided for pieces that encourage the sociological eye to focus and thoughtfully speculate on the emerging patterns, current events, or long-term trends that constitute our social worlds. Such a glaring gap in the literature makes the appearance of *Voicing Social Concern* especially valuable. Within its pages readers will find 33 considered and often provocative commentaries offered by well-known scholar Otto N. Larsen.

These essays were originally presented as talks during Larsen's worldwide travels. They span a 40-year period and together address a wide variety of topics, including censorship, human relations, innovation and productivity, media violence, political elections, pornography, and the future of sociology. They are straightforward, clear, and void of professional jargon. Indeed, in the author's own words, they represent and attempt to "convert research ideas into a pertinent message of interest to intelligent people beyond those regularly met in a circle of peers with technical specialties."

Those looking for in-depth treatment or complex theoretical excursions will be disappointed by the volume. But those searching for ways to jump-start critical thinking will find it a useful tool. Despite the broad time period from which the writings are drawn, Larsen's essays raise fresh, insightful questions on currently pressing issues. For example, even though his essay on the effectiveness of communication, "Trying to Be Effective — Vying to Be Successful," is over 30 years old, the issues Larson probes remain at the heart of cultural sociology and communication discourse. In some cases the essays exemplify the intellectual creativity generated when one merges nontraditional "data" with key sociological concerns. "Comic Books and Creative Leisure" provides one such illustration. And often these commentaries afford the opportunity to retrace thinking on key issues such as pornography, sex, violence, and sociology itself. In so doing, Larsen's work provides a basis by which to enhance the fruits of future action.

Both the content and style of this book make it suitable for advanced undergraduate courses as well as graduate seminar classes. In each of these arenas the Larsen essays could easily serve as an entree to more in-depth treatments of the matters at hand. And whether one agrees or disagrees with Larsen's views, *Voicing Social Concern* is sufficiently engaging to capture the reader and spark subsequent meaningful discussion.

Interpreting the Field: Accounts of Ethnography.
Edited by Dick Hobbs and Tim May. Oxford University Press, 1993. 247 pp. $24.00.

Reviewer: MARTHA COPP, *East Tennessee State University*

When this book arrived, I envisioned reading some gripping "confessionals." For students and seasoned field-workers alike, fieldwork accounts can be engaging without forcing one to get one's hands dirty or to make sense of the data. They may also fill readers with envy or prod them to improve their work. When confessionals combine scholarship and self-help with an analytical hook, many gobble them up. But as I have learned, when accounts lack analytical purpose, they can bore a reader silly. The eight essays in *Interpreting the Field* offer unequal thrills. Some contributions are excellent and coherent, some contain momentary insights, and others are sedatives.

The authors of this collection represent varied disciplines: sociology, anthropology, criminology, geography. In addition to telling familiar stories of getting in, getting along, and getting finished, they explain the social conditions under which they did their work. All conducted fieldwork in Britain, all tried to be sensitive to politics and social class, and all revealed ethical uneasiness despite covert or overt research practices. The researchers also attempted "reflexivity" by treating themselves as sources of data. Because their essays differ in substance and quality, individual summations follow.

In the lengthy lead essay on studying hooligans, Gary Armstrong narrates reflexively but lacks analytical focus. Dick Hobbs details how the tone and content of his writings shifted to suit different audiences as he gained academic footing. Tim May critiques unemotional traditional ethnography but provides cryptic examples from his work on the probation service. Arguing inconclusively that openly partisan researchers can obtain good data, socialist researcher Penny Green revealed her views only to those she sided with in a miners' strike. With welcome clarity, Clive Norris incisively discusses the ethical dilemmas he resolved while studying the police. Jane Fountain follows with a looser and longer exploration of her admittedly unethical strategies to research cannabis dealers.

Sasha Roseneil's essay on studying the women's peace encampment at Greenham Common provides the book's strongest examples and arguments in favor of reflexive research. And in the poignant final essay, H.L. Ackers demonstrates how she distorted and weakened her analyses by separating her personal life from her research, writing only what an academic audience would deem acceptable. Both Roseneil and Ackers successfully consider how their gender and sexuality mattered (Ackers also considers her race); and, less directly, May looks at how masculinity may have affected his research. As a result, their three essays seem more complete than the other accounts.

Ideally, all the authors should have written reflexive ethnographies. Although some did, many did not, citing the fear and pressure of the rigid academic generalized other. As long as field-workers keep official analyses uncontaminated by "personal" feelings and experiences, they will feel compelled to write separate confessionals, as in this volume. Nevertheless, the essays in *Interpreting the Field* suggest that such practice is becoming increasingly unsatisfactory because the standards of good ethnography now include being reflexive. Recommended for

patient students and established field-workers, the accounts in this collection shed light on how to achieve those higher standards.

Peacekeepers and Their Wives: American Participation in the Multinational Force and Observers.
By David R. Segal and Mady Wechsler Segal. Greenwood Press, 1993. 181 pp. $59.00.

Reviewer: JAMES BURK, *Texas A&M University*

The use of armed forces for peacekeeping has been a matter of increasing interest since the end of the Cold War. Such interest is practical as policy makers try to determine how armed forces may be used to minimize collective violence around the world. This issue is theoretical as well, especially for sociologists. Armed forces are changing institutions. In recent years they have expanded their mission from fighting wars to participating in operations other than war. Yet few careful analyses of how this change has occurred and how it has affected related institutions exist. The new institutionalism has yet to embrace studies of the military. This book is an exception. Working from a social constructivist perspective, the authors have labored since the early 1980s to place the involvement of U.S. forces in peacekeeping into historical context, to indicate the organizational adaptations required to deploy war fighters as peacekeepers, and to trace the consequences of peacekeeping deployments on the wives left behind. (The focus on wives alone is justified, as no women were deployed in the peacekeeping mission studied.)

The book is organized into three parts. In the first Segal and Segal review the history of peacekeeping in the West from the League of Nations to the present and set the stage for understanding the role of the U.S. as peacekeepers deployed in the Sinai between Israel and Egypt. In part 2 they describe an elaborate comparative study of elite paratroopers and light infantry fighters as the latter prepared for deployment, were deployed, and returned from peacekeeping. In part 3 the authors consider how the wives of peacekeepers adjusted to the deployments.

Two major findings follow from this research. First, peacekeeping led soldiers to see the world in more peaceful terms. This was true for both paratroopers and light fighters, although paratroopers retained a more bellicose worldview. Nevertheless, there was no strong relationship between a soldier's combat orientation and his attitude toward peacekeeping. More important to predicting a soldier's acceptance of the peacekeeper's role was the belief that his peacekeeping experience would enhance his career. Second, wives believed the deployment changed their own lives. Most reported increased personal growth and greater independence; and they expected to keep their freedom when their husbands returned home, though many were disappointed. Whether wives adjusted well to peacekeeping deployment depended in part on their coping style, but contextual variables were also important. Those who were well connected to the military community during deployment adjusted better than those who were not. Connections affirmed the importance of the peacekeeping mission, giving meaning and legitimacy to the sacrifices of the well connected, a comfort that the poorly connected lacked.

On balance, the authors of this study have done a good job describing what peacekeeping deployment means for the daily lives of soldiers called on to perform the mission and what it means for their families. It is an essential and welcome contribution that should encourage further study about how the military's use in peacekeeping has altered its institutional self-understanding and its relation to the larger society.

Crime and Its Social Context: Toward an Integrated Theory of Offenders, Victims, and Situations.

By Terance D. Miethe and Robert F. Meier. SUNY Press, 1994. 209 pp. Cloth, $57.50; paper, $18.95.

Reviewer: ROBERT M. O'BRIEN, *University of Oregon*

In *Crime and Its Social Context,* Miethe and Meier attempt to integrate offender-, victim-, and context-based theories of crime into a single theoretical perspective. The criminal act is the dependent variable — not offenders, not victims, and not crime "hot spots" or the social relationships between victims and offenders. To explain the criminal act "requires attention to offenders and to victims, but it can never be complete without a sense of the context in which criminal acts take place." The authors address their task at both the conceptual and empirical levels. Their strategy, much like Cohen and Felson's routine activity approach, pays attention to motivated offenders, suitable targets (victims), and the absence of capable guardians (context) — components often ignored in empirical research.

In the two chapters that follow their introduction, Miethe and Meier describe theories of criminality, victimization, and criminal opportunities. Their summary of these theoretical perspectives is excellent and concise. In chapter 4 they integrate and enhance the perspectives. The model of criminal events that emerges includes sources of offender motivation, victim characteristics that provide criminal opportunities, and the social context (physical locations, interpersonal relationships, and behavioral settings) as factors affecting the probability of criminal events. The authors emphasize that these factors interact to create the probability of a criminal act.

In chapters 5 through 8 Miethe and Meier examine data from a variety of sources: uniform crime reports, national crime surveys, the U.S. census, and their own victimization study. Sometimes they make simple descriptive comparisons of results from these varied sources; at other times they make overtime comparisons; and at still other times they compare census tract–level analyses with city-level and SMSA-level results. Space limitations preclude reporting these results, which come from different analytic techniques, but we should be encouraged by similarities in the findings at several levels.

In chapter 9 the authors exploit their data from a Seattle telephone survey. This survey is unique in its range of questions and in its sampling design, which allows estimates of block-level characteristics to be computed. The authors first present logistic regression analyses of an individual's risk of victimization for various types of crimes. These equations include several individual-level variables, such as age, gender, race, nights spent out, home unoccupied, dangerous activities, living alone, and family income. They then add several

block-level characteristics, such as residential mobility, busy places, ethnic heterogeneity, low socioeconomic status, mean nights out, and mean value of carried valuables. The authors find that both individual-level variables and contextual (block-level) variables are important determinants of an individual's risk of victimization. For example, a person's risk of being robbed or mugged is negatively related to that person's family income and positively related to the socioeconomic status of the block on which he or she lives That is, family income is associated with less risk of an individual falling victim to these crimes, even when controlling for the socioeconomic status of the block on which the person lives. For burglary and auto theft, both the individual's family income and the socioeconomic status of the block on which the person lives are related positively to victimization risk. These are indeed interesting and meaningful findings.

Next the authors examine interactions by dichotomizing context-specific block-level variables, such as family income (low/high) or busy places (low/high). They find that "having safety precautions" lowers risks of burglary in high-income but not in low-income areas. Safety precautions do not lower burglary risks in busy places, but they do in less busy ones. These and several other interactions demonstrate the importance of context in determining which factors influence the risks of crime.

Overall this is an excellent book. Miethe and Meier demonstrate that many empirical analyses of rates of crime have been misspecified, because the analyses have not taken into consideration *simultaneously* criminal motivation, victim availability, and the social and physical context in which criminal acts occur.

A Festival of Violence: An Analysis of Southern Lynchings, 1882-1930.
By Stewart E. Tolnay and E.M. Beck. University of Illinois Press, 1995. 297 pp. Cloth, $49.95; paper, $19.95.

Reviewer: KENT REDDING, *Indiana University*

Between 1880 and 1930 mobs lynched between 3,000 and 4,000 southerners, most of them African Americans. Since the end of the lynching era dozens of books and scores of articles have been written about one or more of those mob murders. Although Tolnay and Beck's important book is unlikely to stabilize what appears to be a burgeoning scholarly interest in this grisly phenomenon, it is by far the most sophisticated and sustained quantitative analysis to date of the structural correlates of southern lynchings.

Readers who have followed the authors' spate of articles on the topic in various journals will not be surprised by many of the findings reported in their recent book. Still, *A Festival of Violence* is no mere compilation of previously published work, nor is it a dry reportage of statistical findings. While the writing is sometimes plodding and repetitive, the authors generally do an effective job of integrating the various strands of their previous work and of dramatizing their concerns by weaving into the text narratives of particular lynchings.

Their basic concern is explaining the considerable variation in lynchings across 50 years and 800 or so counties in 10 states (Texas and Virginia are omitted because of data problems; Kentucky is included as part of the South). Initial chapters provide historical background and descriptive statistics and sketch the

basic conceptual model. The heart of the book lies in four chapters, three devoted to testing components to the "threat perspective" of race relations and one to explaining the demise of lynching by 1930.

Using a variety of specifications of time-series and cross-sectional models of lynching, the authors reject both popular-justice and political-competition explanations for lynchings. Whereas contemporaries claimed that lynchings were a form of popular justice, Tolnay and Beck find neither a reinforcement nor a substitution effect of lynchings for executions in either time-series or cross-sectional analyses. Moreover, they report a *negative* association between Republican (and even Populist) strength and the number of lynchings, and no significant change in lynching patterns after the implementation of formal disfranchisement measures.

Economic-threat models, derived from Blalock, turn out to provide the best explanations of African American lynching patterns. Tolnay and Beck find lynching associated with lower cotton prices over time, cotton dominance and white landlessness across counties, and seasonal demand for labor. These associations reflect both the need of white planters to control black laborers and the economic competition between poor whites and blacks.

Finally, Tolnay and Beck argue that the number of lynchings declined not because of antilynching activism, the advent of New Deal agricultural policies, or improvement in law enforcement. Rather, they find a reciprocal relationship between the great out-migration of African Americans and lynching in the 1910s and 1920s: lynching increased out-migration, and the increase in out-migration resulted in fewer lynchings, as fear of labor shortages may have induced white planters to curtail mob violence.

Fortunately, in the authors' hands conventional statistical techniques are not used as blunt instruments but as tools for testing and contextualizing theoretical and historical explanations. By using their various statistical models in historically sensitive ways, they have significantly advanced our understanding of the patterns of lynching without ignoring the complexities of southern history.

That said, historian W. Fitzhugh Brundage's recent work on lynchings in Virginia and Georgia may lead one to wonder if Tolnay and Beck are justified in treating all lynchings the same, given the different social organization of the mobs used to accomplish them. Contrary to what one might have surmised from having read Tolnay and Beck's book, according to Brundage mass mobs with broad community support were involved in a minority of lynchings in Virginia and Georgia.

Furthermore, in spite of Tolnay and Beck's skillful and nuanced use of regression models, those used in historical research have limitations. In this case they explain the correlates of lynching without explaining the processes, either of how lynchings became the established means for controlling the economic threat of blacks to whites, or of how they were sequentially related to one another. But such problems await new historical research and the application of new methods. In the meantime, we have *A Festival of Violence* as a fine and definitive work on the social-structural underpinnings of the savagery of southern lynchings.

The Anti-Abortion Movement and the Rise of the Religious Right: From Polite to Fiery Protest.

By Dallas A. Blanchard. Twayne Publishers, 1994. 177 pp. Cloth, $26.95; paper, $14.95.

Reviewer: CLYDE WILCOX, *Georgetown University*

Dallas Blanchard opens this book with a quotation from the *Reader's Digest* that makes it clear that he believes that the pro-life movement is dangerous and that he has an obligation to warn his reader of that danger. It also exemplifies to an extent the author's approach to documentation: a few hours of research would have uncovered a number of quotations from more important sources that would have made his point more clearly. A serious scholarly study of the rise of this diverse, complex social movement would be welcome, but this book appears to have been written hastily, and Blanchard's personal bias frequently comes through.

An example of hasty production can be found in the author's presentation of the history of the burning and bombing of abortion clinics. Blanchard first reveals data indicating that 1992 is *the* crucial year in determining a possible trend toward increasing violence, but he later neglects to include data from 1992 in tables in which he outlines information on arson and bombings separately, although the data are from the same source.

An example of Blanchard's bias occurs in chapter 4, where he writes: "Fundamentalism, then, worships a violent God. . . . The fundamentalist mindset espouses physical punishment of children, the death penalty, and the use of nuclear weapons; fundamentalists are more frequently wife abusers, committers of incest, and child abusers." Although fundamentalists do endorse spanking, capital punishment, and maintaining a nuclear arsenal as a deterrent, the same can be said for a majority of nonfundamentalist Christians, who presumably worship a more peaceful God. As documentation for his claim that fundamentalists abuse their wives and children, Blanchard references an unpublished 1988 conference paper and a 1960s psychiatric study of some 60 families of widely diverse religious backgrounds in which the authors claim the following: "*It is our impression* that *among those who were actively involved in their religion*, there was a greater than average adherence to . . . fundamentalist religion" (emphasis added). This is sparse support for a bold assertion.

Blanchard frequently blurs important distinctions — between the potential constituency of the pro-life movement and actual organizations and activists, between the Christian Right and the pro-life movement, and less frequently between Catholics and fundamentalists in the pro-life movement. For example, he argues that "the earliest explanation for the movement was that participants were members of the working class attempting to shore up, or defend, their declining social status." As support for his argument he cites Gusfield's classic book on the temperance movement and Lorentzen's analysis of the school book controversy in Charleston, West Virginia, but neglects research in which this explanation in used in relation to antiabortion groups.

When Blanchard attempts to get at the motivations of the actors in the movement, his argument is confusing. His list of "fundamentalist issues" is not a list of fundamentalist positions on reproductive issues, for it includes foreign

policy, but it is also surely not a list of major issues for fundamentalists, since it excludes education and is heavily weighted to reproductive issues, including contraception, which Blanchard incorrectly claims fundamentalists oppose. What precisely is this list supposed to represent?

Blanchard provides an overview of the major social movement theories that could explain the pro-life movement, as well as a history of abortion and the rise of the pro-life movement. But his coverage is superficial and leaves interesting questions unanswered. For example, soon after stating that the initial reaction to the *Roe* v. *Wade* decision in 1973 came from Catholics, he writes that most opponents of the decision are Protestant fundamentalists. How did orthodox Protestants become involved in what was initially perceived by many to be a "Catholic issue"? How did pro-life organizations grow and proliferate?

The most valuable part of the book is a list of major pro-life organizations and their addresses in the appendix. Blanchard also provides some descriptions of the organizations in the text, although they are uneven and often drawn from secondary sources.

Inventing the Feeble Mind: A History of Mental Retardation in the United States. *By James W. Trent*. University of California Press, 1994. 356 pp. $30.00.

Reviewer: BRUCE BELLINGHAM, *Florida State University*

Clearly the authoritative work on the institutional history of mental retardation from the beginnings of special education to the present, *Inventing the Feeble Mind* is also a fine example of "cultural constructionist" policy analysis. Without glib nominalism, James W. Trent treats retardation as a social fact, and his analytic treatment is enlivened by a mature sensitivity to moral issues. Teachers of social problems, health policy, or historical methods who expose advanced students to the constructionist research tradition could hardly find a better exemplar.

Eighteenth-century idiots enjoyed a protected place in local communities, but by the Jacksonian era, Trent reports, vocational complexity and urbanization made mental impairment more awkward. Yet modernization also brought the promise of amelioration. Scientific educators like the expatriate French "physiological" pedagogue Edward Sequin — whose experiments and methods still constitute the greater part of special education's repertoire — made brilliant progress. These charismatic Victorian special educators, working in intimate contact with small groups of resident pupils, made miraculous progress with apparently hopeless cases. Nonetheless, their successes commenced more than a century of custodial warehousing and gross abuses of power.

Different epochs in the prolonged tragedy of retardation are marked by a sequence of governing images or rhetorics. Trent links these shifting images to the evolving professional strategies and ambitions of the medical directors claiming jurisdiction over idiocy. Economic elites also played a surprisingly active role in shaping policy and the human sciences of impairment. Links between the practical and ideological enterprise of mental hygiene and the culture of the natural sciences pose sociology-of-knowledge issues that Trent handles with aplomb.

A summary simplifies Trent's subtle arguments. Briefly, a vast program of institution building was warranted by the useless idiot who burdened the productive capacity of the natal family and community in the rebuilding effort after the Civil War. The criminal (male) or sexually profligate (female) hereditary "menaces" of the Progressive Era eugenics scare implied broad social control of immigrant and lower-class populations. The normalizable idiot of the interwar years was a creature of the need to cycle "paroled" inmates out of institutions in response to higher intake rates and of a professional desire for new roles in community mental hygiene. In 1970, wrongly incarcerated mentally challenged citizens were discovered coincident with prohibitions on using inmates for unpaid in-house labor and with fiscally motivated state wishes to release them — thereby off-loading special-education costs to the federal government, which has sustained the custodial bias through payments to private service providers. No coherent attempt was ever made to define or serve the interests of the retarded themselves.

Paradoxically, the germ of this failure traces beyond the bustling "medical man" managers of the late nineteenth century to the heroic Victorian special educators. The Victorians did some good, but by adopting a limited medical model of impairment and by focusing on particular symptoms of defect and discrete therapeutic techniques, they defined the idiot and his or her social and economic roles and prospects as therapeutically irrelevant. A limited, technical vision facilitated exaggerated professional claims, consequent institution building, and routinization of training. It also resulted in substantive irrationality being inserted into policy: apart from smooth institutional functioning, mental hygienists could not state the purpose of treatment. The question of purpose raised broad social issues about family life and labor markets that medical officers kept at bay for over a century.

That such a faulty project endured suggests that the asylums offered solutions to practical problems arising in the community and family. Trent skirts demand-side agency, however, stressing instead medical mystique and salesmanship. One poignant but untheorized discussion of parental estrangement from institutionalized children offers a tantalizing glimpse of the richness of the records (as do the eugenists' own distorted "case histories"). But questions from the interactionist tradition of sociology are missing. For example, at midcentury idiots were all males. Hereditarian discourses of sexual dangerousness later warranted recognition of female idiots, Trent argues. Interactionist accounts of the micropolitics of trouble preceding deviant classifications suggest that the changing character of domestic conflicts involving girls might have had more to do with the invention of female idiots than scientific models did. Indeed, intake pressures are noted as a prod to entrepreneurial innovation, but the sources of this pressure remain mysterious. Trent cannot explain why female idiots were suddenly recognized because situated interactions connecting family and community to the institution are beyond the boundaries that constructionism imposes on itself. A history of the retarded has still to be written. But this history of their keepers is splendid.

Paths to Homelessness: Extreme Poverty and the Urban Housing Crisis.
By Doug A. Timmer, D. Stanley Eitzen, and Kathryn D. Talley. Westview Press, 1994. 210 pp. Cloth, $55.00; paper, $16.95.

Reviewer: JAMES WRIGHT, *Tulane University*

Does homelessness stem from the personal deficiencies of homeless people or from problems and dislocations in the larger social structure? Some two dozen volumes published in the last decade argue in favor of the latter viewpoint, which most sociologists would find self-evident. Given the quantity of recent material on the homeless, one wonders whether anything worthwhile remains to be said.

The value of *Paths to Homelessness* is not that it contains major new insights; social scientists conversant with recent literature on homelessness will find themselves in familiar terrain. Timmer, Eitzen, and Talley argue that homelessness results from an increasing rate and depth of urban poverty coupled with a precipitous decline in the supply of low-cost housing; if anything, federal policies on housing, income, welfare, and homelessness have aggravated the problem. Explanations that focus on the personal disabilities of homeless people — their rates of alcohol and drug abuse, mental illness, social estrangement, and the like — are rejected as "blaming the victim." The authors thus present a very different line of argument from that advanced by Baum and Burnes in their 1993 book, *A Nation in Denial* (which, ironically, was also published by Westview Press though not cited in the present work).

What distinguishes this volume from its many worthy competitors is the authors' coupling of social-structural insight and argumentation with qualitative data derived from ethnographic interviews with homeless people in Tampa, Denver, and Chicago. Unlike studies based on "impersonal" survey data, this one gives voice and humanity to homelessness by letting homeless people speak on their own terms. Unfortunately, the authors command neither the ethnographic brilliance of Elliot Liebow (*Tell Them Who I Am*, 1993) nor the journalistic rage of Jonathon Kozol (*Rachel and Her Children*, 1988), both of whose evocative portrayals succeed as literature and as social science. In comparison, *Paths to Homelessness* is rather flat and ultimately unsatisfying.

One concern is that the authors' efforts to create sympathy for the homeless will have an opposite effect on many readers. For example, in a discussion of "middle class moralisms about appropriate behavior" that shelter providers frequently attempt to enforce, the apparently incredulous authors tell the readers that "one of the shelters instituted a policy of not paying for children's drug prescriptions if their parents were spending money on cigarettes." In the same vein, the authors relate the following: "*Interviewer:* How do you feel about the way the shelter treats you? *Diane:* I mean its not like livin' in luxury. You have to like almost earn your keep if you stay here." Diane's reference is to the obligatory chores that people who live in the shelter are expected to perform: make their own beds, wash dishes, mop floors. She adds a bit begrudgingly, "The dishes have to be done by somebody, so it might as well be us because we ate." I have no doubt that the authors meant to depict Diane sympathetically, but in their portrayal she comes off as an ingrate.

Diane is not an isolated example. Many of the homeless people whose stories are recounted here appear less as the unfortunate victims of large-scale social

forces than as foul-mouthed whiners who expect simply to be given whatever they think they need. In more than a few cases, the authors' attempts to dismantle stereotypes inadvertently reinforce and amplify them, a problem aggravated by what might be called the "shit-fuck-asshole-cocksucker" approach to urban ethnography, where the informants' every vulgarity is faithfully reproduced — a style more tedious than offensive.

Paths to Homelessness is a capable overview of the arguments and research literature depicting homelessness as a social-structural problem. Readers seeking the voice of the homeless, however, will be better served elsewhere.

World Changes in Divorce Patterns.
By William J. Goode. Yale University Press, 1993. 354 pp. $35.00.

Reviewer: FRANCES GOLDSCHEIDER, *Brown University*

Goode has given us a treasure — a systematic description of trends in various aspects of divorce for many of the world's regions between 1950 and 1990. He provides a wide array of information, drawn mostly from official statistics and documents. His book contains an introduction, a conclusion, and nine chapters that each address a particular grouping of countries (with groupings based primarily on similarity of institutions, culture, and history). Most countries for which reasonable data on divorce over time exist are included in the study.

Europe gets four chapters: the Nordic countries, the Catholic south, the (formerly) Communist East, and a core residual, which is "the general pattern" for the world. These chapters are followed by two on Europe's great areas of cultural conquest: the English and Iberian blocks. The rest of the world is represented in three chapters containing special groupings: Japan and Malaysia, the "Arab world," and Indonesia, Taiwan, and China.

The topics covered in each chapter necessarily vary to a certain extent, but Goode generally includes information on changes in divorce rates, the legal system, the average duration of unions ending in divorce, children's involvement, remarriage and cohabitation, and postdivorce arrangements. This framework works well for the most part, allowing Goode to be both thorough and particular.

So what is not in the book? That is not a fair question, since every piece of research is necessarily selective. Given that "world" is included in the volume's title, however, it is reasonable to raise questions about the author's choice of countries. Further, on behalf of the generations of family scholars who learned about "convergence" from Goode, it is important to address the theoretical framework of his study.

Goode tells us that the data do not allow comparable analysis (even at the level of the Latin American chapter) for Africa or southern Asia. The same probably holds for the adjacent countries, including much of Southeast Asia. Yet Thailand has had a modern data-collection system throughout most of the period reviewed and may represent its more disrupted neighbors on many dimensions, but it is not mentioned. More puzzling is the omission of Greece. Presumably these countries did not fit the grouping framework.

However, William Parrish has provided a reconsideration of Goode's framework, which suggests that the more countries included the better. Using basic

regression analysis, Parrish shows that Goode's nine groupings really come down to three sets clustering around very tight regression lines. One group has responded little or slightly negatively to increases in conventional indicators of industrialization (the Arab and Moslem countries), and two have responded positively to them (Eastern Europe, starting from a high level, and the rest of the world, starting from a lower level).

What accounts for these patterns? Why should divorce rates decline in some places before rising, which Goode correctly indicates was even the pattern in Europe under Catholicism? Perhaps if Goode had thought as systematically about changes in men's familial roles in the earlier period as he did about those in women's in the modern period, he might have made more connections. His older analysis of the convergence on the nuclear family may provide a key. Perhaps the growth of the nuclear family increased the costs of divorce for women and children. Furthermore, as early industrialization made men increasingly less dependent on family ties and family labor, other still powerful institutions such as the church increased the stringency of divorce in order to tie men effectively to their now more vulnerable wives and children. As women have gained a similar independence with continued industrialization, however, they have developed a greater acceptance of divorce — but as Goode points out, we still have to worry about the children.

Women in Ministry: Receptivity and Resistance.
By Edward C. Lehman Jr. Joint Board of Christian Education (Melbourne, Australia), 1994. 156 pp. Paper, $11.50.

Reviewer: KEVIN J. CHRISTIANO, *University of Notre Dame*

The most satisfying aspect of this small paperback volume about the introduction of female clergy into two Australian denominations is that its author says exactly what he means and clearly means what he says. With this book Edward C. Lehman Jr., an experienced sociologist of religion who has studied the receptions accorded women ministers in the U.S. and Great Britain, extends his research Down Under. Throughout this work he is precise in claiming what he has accomplished at the same time that he is unpretentious in discussing its implications.

"The goals of the undertaking," as Lehman lists them without fanfare in the preface, "were to describe patterns of receptivity and resistance to women as ordained clergy and to identify factors that could explain those differences in attitude" among parishioners in five of Australia's largest states. Of course the obstacles facing women in traditionally male-dominated professions have received extensive coverage in Australia's popular media, as they have elsewhere. And as elsewhere, much of the concern of church leaders in Australia has centered on how — or even whether — age-old disciplines might be modified from the top to better accommodate the aspirations of female members. Scholars of religion have given less attention, however, to measuring the reactions of average churchgoers to the integration of ministries by gender. Lehman's intention, then, was to produce "a study of what ordinary lay church members thought and felt about the issue" of women in the role of priest.

For his national survey, Lehman chose the two largest Protestant denominations in Australia, the Anglican Church and the Uniting Church. The former, as its name implies, derives from the Church of England; the latter is the outcome of a merger in 1977 of Congregational, Methodist, and Presbyterian churches. Initially the two denominations differed markedly in their official postures toward female clergy: whereas the Uniting Church made acceptance of ordination for women an explicit "basis of union" from the outset, the Anglicans, after great controversy and internal division, only recently voted to permit individual dioceses to open the priesthood to women. They still have no policy that is nationally binding.

In his presentation, Lehman moves quickly from simple descriptions of the data to an exposition of bivariate relationships, and from there to statistics generated by multiple regression. Yet he remembers that many of his readers are not social scientists, and so he strains to frame his interpretations in cautious and nontechnical language.

The varied and complex nature of Lehman's results renders an easy summary impossible. However, Australians "as a whole" are "accepting" of women clergy. A minority prefer men to perform priestly functions, but most church members do not care about gender. Instead, they evaluate ministers without obvious reference to sexual stereotypes. "These patterns bode well both for clergywomen and the churches," observes Lehman. "Lay church members show little inclination to burden women ministers with jaundiced perceptions of their ability to do the job."

Lehman finds that opposition to the ordination of women among lay members in the Protestant churches of Australia is connected to conventional attitudes toward sexuality, the negative opinion of a member's own pastor on the subject, and a low degree of salience for the issue itself. More specifically, "it is difficult to overestimate the influence priests and pastors can have on their lay church members." "What they say about the ordination and placement of women as priests and pastors tends to carry more weight than any other single factor."

This book is not a full-length monograph on perceptions of the clerical profession in Australia. Rather, most of the analysis reads like the final memorandum of a researcher to his or her client. Alert readers nevertheless will learn something in passing about the structure of Australian religion. In addition, Lehman furnishes a valuable, if short, section of comparisons between the results of his Australian survey and those of his research in other societies.

Finally, thanks to the care with which Lehman recounts his research process and to appendixes in which his original questionnaires (with marginal frequencies added) are reprinted, readers who have no direct interest in gender, occupations, or religion will at least gain a brief tutorial on the conduct of a small-scale survey project.

Leaving Home Before Marriage: Ethnicity, Familism, and Generational Relationships.
By Frances K. Goldscheider and Calvin Goldscheider. University of Wisconsin Press, 1993. 242 pp. $27.50.

Reviewer: DANIEL T. LICHTER, *Pennsylvania State University*

For most of American family history, young adults have typically resided with their parents until marriage. In *Leaving Home Before Marriage,* Goldscheider and Goldscheider argue that independent, nonfamily living is now a normative though fragile stage of young adulthood. Basing their findings on the 1980 High School and Beyond Survey, they report that nearly 70 percent of high school seniors expected to live apart from their parents before marriage. Indeed, about 50 percent actually became residentially autonomous within six years of graduating from high school. Another 30 percent married, and 20 percent remained residentially dependent on their parents.

This book has several interesting features. It is probably the first comprehensive treatment of premarital residential independence, arguably the best marker today of the transition to adulthood. Goldscheider and Goldscheider dispel the popular view that young adults are returning to the nest in large numbers; unmarried young adults today are less likely than those in the past to live with their parents. The authors examine the important influences of parents' expectations and financial resources on independent living among their children. Finally, they pit economic explanations that emphasize the effect of affluence on residential autonomy against cultural explanations that stress ethnicity, familism, and egalitarianism.

Although *Leaving Home Before Marriage* is useful, well written, and provocative, the analyses and results sometimes provide a weak basis for strong conclusions. The main one is the most overdrawn and contentious. The authors give only modest support to the hypothesis that rising affluence has allowed young adults to "buy" independent living and privacy. Instead, they conclude "that affluence is much less important than values" and "that nonfamily living has simply not been as well accepted in more familistic ethnic groups and more familistic religious denominations as it has been in the dominant, largely secular culture." However, the evidence they present to support the emphasis on values over affluence is weak.

First, the authors measure parental "affluence" rather than the changing economic circumstances of the young adults themselves (i.e., employment, earnings, and school enrollment). Does going to college, finding a job, or becoming unemployed affect premarital residential independence? Do earnings or access to welfare during young adulthood? These are obvious questions to answer before asserting that values predominate over economic circumstances in influencing nest-leaving.

Second, my interpretation of the results is that parental affluence (as measured by socioeconomic status) has a large — not small — effect on nonfamily living. Although parental socioeconomic status is only minimally related to parents' expectations about their children's nest-leaving, it is strongly related to actual behavior. Among children in the lowest decile of socioeconomic status, 50 percent achieved independence within six years of high school graduation,

compared with 81 percent among those in the highest decile. In the bivariate analysis, parental socioeconomic status had the largest absolute effect on premarital independent living — larger than the effects associated with any of the measures for values (i.e., familism, secularization, or egalitarianism).

Third, rather than measuring values directly, the authors use demographic variables as proxies: familism is measured by ethnicity and region; secularization is indicated by one's religious affiliation and denomination; and egalitarianism is measured by gender. Truly convincing conclusions about the importance of values over economics requires a thorough analysis of attitudes about the desirability of marriage; the need for personal privacy, autonomy, and fulfillment; past parent-child relationships (i.e., conflict); and gender roles (i.e., attitudes about female dependence). Indeed, the multivariate analyses indicate that only about 10 percent of the variance in nonfamily living can be explained by the proxies. More and better measures of affluence and values are needed to support the kinds of strong arguments Goldscheider and Goldscheider make.

Fourth, the analysis is based largely on seniors interviewed in the 1980 High School and Beyond Survey; dropouts are excluded. The problems of bias associated the exclusion are potentially serious, in large part because dropout rates differ significantly across various racial and ethnic groups. In 1980, for example, about one-third of Latino males (aged 16 to 24) were high school dropouts, compared with about 15 percent of white males. Can the authors then claim that familistic ethnic groups — like Latinos — are less likely than other ethnic groups to become residentially independent before marriage? How do living arrangements change when Latino men drop out of school? Do they continue to live with their parents? Do they drop out of school to get married or to work? And how does their reason for dropping out affect routes to residential independence? Dropouts cannot be ignored in a self-proclaimed "comprehensive" treatment of premarital nonfamily living.

Despite its limitations, *Leaving Home Before Marriage* is interesting and thought-provoking. The authors draw attention to an increasingly significant life-cycle stage of young adulthood and provide a point of departure for additional research on many relevant questions about the timing, causes, and economic implications of nest-leaving.

Feminist Organizations: Harvest of the New Women's Movement.
Edited by Myra Marx Ferree and Patricia Yancey Martin. Temple University Press, 1995. 474 pp. Cloth, $49.95; paper, $22.95.

Reviewer: REBECCA E. KLATCH, *University of California–San Diego*

This is a collection of 25 essays originally presented at a 1992 conference on feminist organizations. Case studies are wide-ranging and include examination of the Catholic Church, the Chicago Women's Liberation Union, domestic violence organizations, feminist health clinics, rape crisis centers, post–World War II black women's groups, and antifeminist organizations.

The contributors raise important questions about such fundamental issues as the possibilities and dilemmas faced by feminist organizations interacting with the state, the prospects of organizing across class and race, and the inherent

conflicts involved in building coalitions. Many call into question the dichotomy of radical versus mainstream, challenging the assumption that becoming an insider necessarily means co-optation.

Some essays are more theoretically provocative than others. Reinelt's case study of the battered women's movement in Texas raises key issues regarding the tension between the autonomy of feminist organizations and engagement with mainstream institutions. Staggenborg's essay is exemplary in her linking of empirical cases with theory. Analyzing what types of feminist groups lead to what kinds of outcomes, Staggenborg persuasively argues that the notion of organizational success needs to be expanded.

Other chapters are interesting as empirical case studies: Farrell offers a fascinating examination of the tensions faced by *Ms* magazine in its attempt to balance the feminist interests of readers with the interests of capitalist advertisers. Whittier's study of microcohorts in the Columbus women's movement illustrates how turnover of membership redefines feminist collective identity.

One of the most interesting sections of the volume focuses on emotions within organizational life. In an illuminating essay, Verta Taylor makes a powerful argument for recognizing the role of emotions along with instrumental bases for feminist protest. She mentions but does not discuss the negative side of the emotional life of organizations — for instance, how demands for ideological purity can turn women against one another. Luckily, Morgen's examination of feminist health clinics does address the issue of infighting and conflict. In fact, to its credit, the book as a whole is not based on the assumption that if only women led organizations the world would be different. Several case studies demonstrate how women, too, can dominate or reproduce hierarchy.

I have only two complaints. First, more of an effort could have been made in several chapters to draw out the implications of the case studies for organizational and social movement theory. Clearly some essays are better than others at accomplishing this goal. Cheryl Hyde, for instance, does a commendable job of analyzing the varying strategies adopted by nine feminist social movement organizations in countering the antifeminist New Right. The volume also would have benefited from more essays like those by Gelb and Acker, who synthesize main themes and outline directions for future research.

My other problem with the book is that its authors never really come to terms with one of the main questions: What qualifies as a feminist organization? Does a women's bank count as feminist even though the women involved in it do not identify with one another and know little about feminism (see Tom)? Or is it style that makes an organization feminist? Barnett argues that an emphasis on participatory democracy, community, mutual respect, and self-transformation qualifies a group as feminist. But what about explicit goals aimed at changing women's place in the social structure? While it is essential to recognize the importance of class and race, is not some recognition of the role of gender essential for an organization to be feminist? Based on her study of Mexican-American community activists, Pardo argues that groups of women whose members simply become public actors and extend the mother role to incorporate community issues are implicitly feminist, even though many of these women accept the traditional division of labor and assume that men are natural leaders. By this definition right-wing organizations might also be considered feminist. As Jo Freeman contends in the conclusion, empowering women does not alone

constitute feminism. On the other hand, Christensen-Ruffman argues that women engaged with mainstream political institutions should not be considered part of "women's political culture." Such a narrowing of the term merely adds constraint rather than complexity to our understanding of women's politics.

Yet even these problems are provocative in raising critical questions about the meaning of feminism and how to achieve social change. In short, there is much to be gleaned from these instructive essays not only for academics interested in gender, social movements, organizations, and the state but also for activists and practitioners who sustain feminist organizations.

The Selling of Contraception: The Dalkon Shield Case, Sexuality, and Women's Autonomy.

By Nicole J. Grant. Ohio State University Press, 1992. 240 pp. Cloth, $29.95; paper, $15.95.

Reviewer: JULIE BRINES, *University of Washington*

Struggles over women's sexual and procreative rights often take the form of struggles over contraception. As Nicole Grant documents in *The Selling of Contraception*, the story of the Dalkon Shield intrauterine device is an account of one such struggle and its life-and-death consequences. Heralded in the early 1970s as the "superior modern contraceptive," the Dalkon Shield was eventually linked to at least 17 deaths and countless cases of miscarriage, infertility, and internal injury. The case has had a chilling effect on the domestic manufacture and distribution of IUDs. Today only a few such devices are available in the United States; meanwhile, international family planners continue to advocate their use.

In her compelling account, Grant first weaves a social history of modern contraception through the particulars of the Dalkon Shield case (chapter 1 and 2). Representatives of various interests — professional, state, corporate, cross-national — populate the pages of this history, and there is more than enough evidence of greed, ignorance, and malignant neglect to go around. Grant then turns to the testimonials of a "theoretical sample" of 17 women, most of whom used either the Dalkon Shield or another IUD during the 1970s (chapters 3 and 4). Nearly all of these women seemed aware that the use of an IUD involved some risk. Nonetheless, nearly all actively sought out this method of birth control.

Why did these women opt for IUDs over other forms of contraception? Oral contraceptives were rejected at the time because of their links to cancer, stroke, and side effects. Most of the women, though, still desired a birth control method that separated the contraceptive act from coitus. "Coitally independent" methods of contraception, particularly the IUD, relegated fertility control to backstage work, promising to clear the front stage for "fully spontaneous" sexual expression. In short, Grant finds that for the women in her study the decision to use an IUD was linked to a search for sexual autonomy, albeit one bounded by norms that define fully realized heterosexuality in terms of coitus.

Although Grant's analysis is intriguing, her general conclusions are best regarded as provisional (chapter 6). Consider her two primary research questions: "Why did women of diverse backgrounds use the Dalkon Shield?" and "Was this

case an aberration, or did it reflect normal relationships and routine practices within its sociohistorical context?" Grant's sample cannot address these questions. Most of her participants were recruited through a snowball procedure, the mechanics of which tend to attenuate precisely the kind of diversity (variation) among sample members that Grant needs to address her first question. Moreover, evidence indicates that the experience of an IUD-related injury motivated most of the women to participate in Grant's study (75 percent of IUD users in the sample were injured), introducing a selection bias that surely affects whether the testimonials reflect "normal relationships and routine practices." Also troubling is the inclusion of only one woman in the sample who had never used an IUD. The absence of variation makes it impossible to determine whether, for example, IUD users had relationships with their physicians or concerns about sexuality that departed from or resembled those of other women.

Nonetheless, the study raises important issues. As Grant argues in her conclusion, sex will never be safe for women as long as it is viewed as requiring tradeoffs between competing risks (of pregnancy, disease, or birth-control injury). Such tradeoffs, however, seem necessary for heterosexually active, fertile women only in cultures in which sexual activity is centered on the practice of vaginal-penile intercourse. Consideration of alternative heterosexual practices might encourage these women to think of the risks of pregnancy or contraceptive injury in absolute rather than relative terms. It might also remind us of how powerfully norms can frame "choice" or "autonomy," even in the ostensibly private domains of sexuality and reproduction.

Prostitution: An International Handbook on Trends, Problems, and Policies.
Edited by Nanette J. Davis. Greenwood Press, 1993. 403 pp. $79.50.

Reviewer: VALERIE JENNESS, *Washington State University*

The sheer number of books on the history and social organization of prostitution sitting in any university library attests to an ongoing preoccupation with the subject, one that the social sciences and humanities have enjoyed for almost as long as each has been in business. Given this preoccupation, and having contributed to it myself, when I received a 400-plus-page handbook on prostitution to review, I found myself thinking, Does the academy, much less the world, really need yet another book on prostitution? A review of *Prostitution: An International Handbook on Trends, Problems, and Polices* ensures that the answer is a resounding yes.

Nanette J. Davis, a premier scholar in the study of prostitution in the United States, has edited nothing short of an encyclopedic volume focusing on what Gayle Rubin, in an essay published in *Towards an Anthropology of Women* (1975), has identified as the lowest order of the sex/gender system: female prostitutes. As in Vern Bullough and Bonnie Bullough's classic work *Prostitution: An Illustrated Social History* (1978), a wide range of societies that differ in their cultural, religious, social, and legal systems are represented. Written by different scholars from countries across the globe (except Africa and the Middle East), specific chapters detail the social organization of prostitution in Australia, Brazil, Canada, China, England and Wales, Germany, Italy, Japan, the Netherlands,

Norway, Portugal, Singapore, Taiwan, the United States, Vietnam, and (what used to be) Yugoslavia. Each author covers — to greater or lesser degree — nine interrelated themes: social and legal definitions of prostitution, the history and trends of prostitution, the social organization of prostitution, theories of prostitution, the contemporary status and lifestyles of prostitutes, law enforcement related to prostitution, contemporary politics surrounding prostitution, enacted and proposed interventions into the world of prostitution, and policy provisions related to prostitution.

In covering vast geographical and substantive territory, the book "makes no claims for universal representation about prostitution." Nonetheless, anyone reading it will be exposed to both interdisciplinary and international thinking and theorizing about prostitution; a plethora of empirical facts about the history and social organization of prostitution in countries (and cultures) that are very similar as well as in those that are unimaginably dissimilar; the range of factors that place girls and women "at risk" of entering prostitution and vulnerable to physical and psychological harm once they become engaged in it; descriptions of the vast array of institutional apparatuses, from medicine to law, that have been and continue to be used to control those engaged in the exchange of sex for some valued commodity; and the newfound ways in which some prostitutes and their advocates have resisted and responded to the systems that repress and exploit the former, including undertaking and sustaining an international prostitutes' rights movement.

Consistent with the intent of the book, which is "to show some general comparative trends, directions, profiles, and problems in the social control of prostitutes," readers will come away convinced that a number of things about prostitution transcend cultural context and historical moment. One is that prostitution is overwhelmingly an urban phenomenon. Another is that in every country there is a hierarchy among prostitutes, which is delineated by such factors as location, type of client, level of protection, earnings, and visibility. Finally, and most notably, prostitution is intimately and inevitably connected to the political economy of the society in which it exists and to the system of age, gender, race, and class stratification that characterizes the society in which it takes form.

With regard to gender stratification in particular, the international focus of this book underscores three things. First, to study prostitution is to study the status of women vis-à-vis men. As an Italian prostitute notes in Guido Blumir and Agnes Sauvage's *Done di vita — vita di donne* (1980), "A prostitute is not only a prostitute; she is, above all, a woman." Second, "the selective, gender-biased, hierarchical nature of control often exploits and damages women." And third, the criminalization or legalization of prostitution alone does not stop prostitution; indeed, in her introduction Davis notes that "the more attention given to prostitution as a 'significant' and 'special' social problem, requiring extraordinary measures, the less we see the ordinariness of prostitution as a normal response to gender distinctions and market and political inequalities." This observation is underscored by Finstad and Høigård in the conclusion to their chapter on Norway: "The question of prostitution reaches to the very core of our social organization. If prostitution is to be abolished, we must have a society in which women are no longer forced or coerced to use their sexuality as an economic resource, and in which men are not expected to exploit women's

bodies. The gender-based division of labor is an integral part of society's political economy."

If there is any fault with this book, it has to do with omissions. Key themes and lines of research were not sufficiently developed. For example, the authors devote only minimal attention to the ways in which AIDS has interfaced with, and some would say reorganized, prostitution and has led to what one of them terms "prostitutephobia." Similarly, although prostitution is predominantly a female occupation, the social organization of male prostitution deserves more attention than it receives. Finally, and most important, more information on international trafficking, especially among developing countries, would have enhanced the volume. Despite these omissions, however, the book is unquestionably a very valuable resource for academicians, policy makers, and anyone with a general interest in the status of women globally.

Deciding to Be Legal: A Maya Community in Houston.
By Jacqueline Maria Hagan. Temple University Press, 1994. 200 pp. Cloth, $44.95; paper, $14.95.

Reviewer: KIYOSHI IKEDA, *University of Hawaii at Manoa*

In this study Jacqueline Maria Hagan examines the Totonicapan Guatemalan Maya community in Houston, Texas, before and after the enactment and implementation of the Immigration Control and Reform Act (ICRA) of 1986. A participant-observer, she has developed a framework for organizing rich observations and notes on how undocumented workers have responded to becoming legal immigrants in the United States.

Her work is divided into two parts. Part 1 is made up of three chapters, the first of which provides a framework and methodology for research. In it Hagan presents demographic data on the San Pedro Maya for about 1,000 members of the *munincipio* of Totonicapan, and ethnographies for 74 members (32 women and 42 men). A description of these Maya within their original communities follows in chapter 2, along with a discussion of how some pioneers and their families fostered migration to Houston and employment opportunities there. Hagan discusses Juan Xuc's key role in establishing an employment niche for maintenance workers in a supermarket chain and in developing the network of exchanges from Totonicapan to Houston that allowed for circular migration on a stable basis. In chapter 3 the author provides the demographic and economic context within which men and women adapted and explores the role of strong and weak social-network ties in reproducing Mayan culture within work and community circles. She also addresses how "coyotes" and other interested parties promote illegal immigration by sponsoring and supporting migrants who traverse their way into Houston and return from time to time to San Pedro.

Part 2 focuses on the enactment and initial implementation of the Immigration Control and Reform Act. In chapter 4 Hagan discusses sociolegal, administrative, and individual and community responses to its enactment and details how the law is implemented and administered to assist applicants. In chapter 5 she describes how the ICRA affects opportunities among community members (using length of residence in the United States, marital status, residential status in

Houston and Guatemala, and process of integration into the larger Houston community as measures) and how it continues to impact life and work in and around San Pedro.

Hagan's study of how migrants experienced and adapted to life in Houston and San Pedro before and after passage of the ICRA is a major contribution. She does an excellent job explaining how a viable and adaptive immigrant community for newcomers was created and offers a strong analysis of how network ties enabled men to obtain employment within a carefully cultivated, self-regulating environment. She also does well exploring both the relative absence of weak ties outside the Mayan community for women who must turn to domestic work and the role of women in reproducing Mayan culture within the constraints of Houston. The limitations placed on women's physical and social mobility in fostering networks separate from those of men is well documented, and Hagan's investigation into the differential effects of opportunities associated with becoming legal immigrants, as measured by gender, marital status, length of residence, and residential locus and status, represents a useful application of social network theory and legal impact studies.

Anyone undertaking comparative studies of the ways individuals and communities adapt under conditions of legal and illegal migration and the role of third parties in mediating the migration process will benefit greatly from this work. Given the mix of demographic, sociolegal, and migration-process influences over time, Hagan's effort to weave into her study ethnographic reports of individual migrants is valiant. She might have improved her narrative, however, had she chosen to follow closely the stories of some key figures and families and provided only supplemental reports from the others in her attempt to index the range and types of adaptations the immigrants made.

Citizenship and Nationhood in France and Germany.
By Rogers Brubaker. Cambridge University Press, 1992. 270 pp. $35.00.

Reviewer: CRISTINA ESCOBAR, *San Diego*

This book is a fundamental contribution to the study of migration and citizenship in France and Germany as well as to the analysis of modern state and citizenship in general. It is also as an excellent example of comparative historical methodology. As such, this book appeals to a variety of academic audiences.

Initially, Brubaker helps us see the international arena not just as a territorial organization of states, but also as a set of bounded and mutually exclusive citizenry. This second dimension, he says, is commonly obscured by a territorial bias in the definition of the modern state. Then, he goes into the discussion of modern citizenship. He focuses on the formal dimension of citizenship, which in political sociology has been, more often than not, the taken-for-granted institutional framework. Brubaker's significant contribution is to have brought the modern state in its dual dimensions as a territorial organization and as a political organization into the analysis of modern citizenship. Correspondingly, he proposes two ways of understanding citizenship. One is a formal and abstract approach to citizenship as a general membership status and obligation of a permanent resident population of a state. The other is a concrete and substantive

approach that defines citizenship as special membership status where citizens are a privileged subgroup of the population of the state.

Brubaker unravels the different dimensions of citizenship in France and Germany by means of a historical comparative methodology. The distinction between national and state membership might seem artificial in France, where citizenship as a general status (developed by the absolutist territorial rulers) and citizenship as a privileged status (derived from the classical, medieval, and early modern city-state) were joined in the French Revolution and developed together. However, this distinction is crucial for understanding the immigration problems that France faces today. The French assimilationist and expansive tradition of citizenship has created the problem of second and third generation immigrants who have received citizenship but who have not really been assimilated into the French nation. The comparison with Germany is highly revealing. German nationhood, the privileged status, developed previous to and independently from the state as a result of the particular historical features of the political geography of the region. The German differentialist and ethnic-centered tradition of citizenship policy possesses the paradox of second and third generation immigrants unable and mostly unwilling to achieve German citizenship.

This book is also particularly appealing in its effort to show the significance of the cultural dimension of the politics involved in the definition of citizenship. Even if legislation has been contested, and in some cases modified, Brubaker demonstrates that there are clear continuities, or traditions, in the French and German definitions of citizenship. He argues that these continuities reflect the deep-rooted nature of national self-understanding. He also emphasizes that the traditions are embedded within nonneutral cultural idioms that reinforce and recreate them, producing particular policy outcomes.

Since the author emphasizes that France and Germany are both the exception in Europe, it would have been helpful to have a discussion of the main characteristics of the general context from which they diverge. Nevertheless, Brubaker's contribution to the historical analysis of citizenship in Europe is outstanding.

This book is essential reading for all those involved in the current debate over the future of the nation-state. Whereas others pay attention to the changing characteristics of the international order, Brubaker focuses on deep-rooted traditions. His work makes plain that any reconsideration of the nature and future of the nation-state requires a look at the politics of identity which has played such an important role in the physiognomy of modern Europe.

CRIMINOLOGY

AN INTERDISCIPLINARY JOURNAL

THE OFFICIAL PUBLICATION OF THE
AMERICAN SOCIETY OF CRIMINOLOGY

EDITOR: Charles R. Tittle
Washington State University

EDITORIAL POLICY: The journal is interdisciplinary, devoted to the study of crime, deviant behavior, and related phenomena, as found in the social and behavioral sciences and in the fields of law, criminal justice, and history. The major emphases are theory, research, historical issues, policy evaluation, and current controversies concerning crime, law, and justice.

Clearinghouse on Rural Education and Small Schools

How Schools Can Engage Hispanic Communities

In a new book published by the ERIC Clearinghouse on Rural Schools, Andrea B. Bermúdez of the University of Houston explains reasons and strategies for involving Mexican American and other Hispanic parents in the schooling of their children.

In *Doing Our Homework: How Schools Can Engage Hispanic Communities,* Bermúdez begins by describing the evolution of parents' role in American educatiõn since the century — a time when the country was experiencing a large influx of immigrants. Now, a century later, we continue to face the challenge of addressing the needs of recent immigrants.

Bermúdez provides guidance for educators based on her own research and the research and practice of others. She explains our changing understanding of the role of parents and the persistent barriers to involvement that schools must work to overcome. Strategies include training programs for parents and teachers, model programs for home-school-community partnerships, and collaborations between institutions of higher education and school systems. As Bermúdez points out, in too many places, classrooms have become battlegrounds of competing value systems, learning styles, languages, and attitudes about ethnicity. The casualties have been Hispanic and other minority students who leave school before graduating.

In response, American educators have begun a search that has led some to discover the powerful role parents — including parents who speak little or no English — can play in advancing educational goals. Bermúdez shares their discoveries in this concise (only 91 pages) new resource.
